|                    |                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>iosFdValue()</i> – validate an open file descriptor and return the driver-specific value     |
| <b>SYNOPSIS</b>    | <pre>int iosFdValue (     int fd /* file descriptor to check */ )</pre>                         |
| <b>DESCRIPTION</b> | This routine checks to see if a file descriptor is valid and returns the driver-specific value. |
| <b>RETURNS</b>     | The driver-specific value, or ERROR if the file descriptor is invalid.                          |

## *iosInit()*

**NAME** *iosInit()* – initialize the I/O system

**SYNOPSIS**

```
STATUS iosInit
(
 int max_drivers, /* maximum number of drivers allowed */
 int max_files, /* max number of files allowed open at once */
 char * nullDevName /* name of the null device (bit bucket) */
)
```

**DESCRIPTION** This routine initializes the I/O system. It must be called before any other I/O system routine.

**RETURNS** OK, or ERROR if memory is insufficient.

**SEE ALSO** *iosLib*

---

## *iosShowInit()*

**NAME** *iosShowInit()* – initialize the I/O system show facility

**SYNOPSIS** `void iosShowInit (void)`

**DESCRIPTION** This routine links the I/O system show facility into the VxWorks system. It is called automatically when `INCLUDE_SHOW_ROUTINES` is defined in `configAll.h`.

**RETURNS** N/A

**SEE ALSO** *iosShow*

## ***ioTaskStdSet()***

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>ioTaskStdSet()</i> – set the file descriptor for task standard input/output/error                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <pre>void ioTaskStdSet (     int taskId, /* task whose std fd is to be set (0 = self) */     int stdFd,  /* std input (0), output (1), or error (2) */     int newFd   /* new underlying file descriptor */ )</pre>                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | This routine changes the assignment of a specified task-specific standard file descriptor <i>stdFd</i> (0, 1, or 2) to the specified underlying file descriptor <i>newFd</i> . <i>newFd</i> should be a file descriptor open to the desired device or file. The calling task will use this new assignment when doing I/O to <i>stdFd</i> , instead of the system-wide global assignment which is used by default. If <i>stdFd</i> is not 0, 1, or 2, this routine has no effect. |
| <b>NOTE</b>        | This routine has no effect if it is called at interrupt level.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SEE ALSO</b>    | <i>ioLib</i> , <i>ioGlobalStdGet()</i> , <i>ioTaskStdGet()</i>                                                                                                                                                                                                                                                                                                                                                                                                                   |

---

## *ipAttach()*

**NAME** *ipAttach()* – a generic attach routine for the TCP/IP network stack

**SYNOPSIS**

```
int ipAttach
(
 int unit, /* Unit number */
 char * pDevice /* Device name (i.e. ln, ei etc.). */
)
```

**DESCRIPTION** This routine takes the unit number and device name of an END driver (e.g., "ln0", "ei0", etc.) and attaches the TCP/IP stack to the MUX. If completed successfully, the IP protocol will begin receiving packets from that driver.

**RETURNS** OK or ERROR

**SEE ALSO** *ipProto*

---

## *ipDetach()*

**NAME** *ipDetach()* – a generic detach routine for the TCP/IP network stack

**SYNOPSIS**

```
STATUS ipDetach
(
 int unit, /* Unit number */
 char * pDevice /* Device name (i.e. ln, ei etc.). */
)
```

**DESCRIPTION** This routine removes the TCP/IP stack from the MUX. If completed successfully, the IP protocol will no longer receive packets from the named END driver.

**RETURNS** OK or ERROR

**SEE ALSO** *ipProto*

---

## *ipFilterHookAdd()*

**NAME** *ipFilterHookAdd()* – add a routine to receive all internet protocol packets

**SYNOPSIS**

```
STATUS ipFilterHookAdd
(
 FUNCPTR ipFilterHook /* routine to receive raw ip packets */
)
```

**DESCRIPTION** This routine adds a hook routine that will be called for every IP packet that is received. The calling sequence of the filter hook routine is:

```
BOOL ipFilterHook
(
 struct ifnet *pIf, /* interface packet was received on */
 struct mbuf **pPtrMbuf, /* pointer to pointer to an mbuf chain */
 struct ip **pPtrIpHdr, /* pointer to pointer to ip header */
 int ipHdrLen, /* ip packet header length */
)
```

The hook routine should return TRUE if it has handled the input packet and no further action should be taken with it. If returning TRUE the *ipFilterHook* is responsible for freeing the mbuf chain by calling *m\_freem(\*pPtrMbuf)*. It should return FALSE if it has not handled the *ipFilterHook* and normal processing (e.g., Internet) should take place.

The packet is in a mbuf chain of which a pointer to a pointer is passed as one of the arguments. The pointer to the mbuf should be accessed by dereferencing the pointer to pointer, *pPtrMbuf*. This mbuf chain will be reused upon return from the hook. If the hook routine needs to retain the input packet, it should copy it elsewhere. by using the macro *copy\_from\_mbufs* (buffer, \**pPtrMbuf*, len). *copy\_from\_mbufs* is defined "**net/mbuf.h**"

*pPtrIpHdr* is a pointer to a pointer to a IP header. The pointer to the ip header is obtained by dereferencing *pPtrIpHdr*. The ip header is used to examine and process the fields in the ip header. The fields *ip\_len*, *ip\_id* and *ip\_offset* in the ip header are converted to the host byte order from the network byte order before a packet is handed to the filter hook.

The *pPtrMbuf* and *pPtrIpHdr* are reused upon return from the hook if it is returning FALSE.

Normally you will not be needing to modify *pPtrMbuf* or the *pPtrIpHdr*.

**RETURNS** OK, always.

**SEE ALSO** *ipFilterLib*

---

## *ipFilterHookDelete()*

**NAME** *ipFilterHookDelete()* – delete a ip filter hook routine

**SYNOPSIS** `void ipFilterHookDelete (void)`

**DESCRIPTION** This routine deletes an IP filter hook.

**SEE ALSO** `ipFilterLib`

---

## *ipFilterLibInit()*

**NAME** *ipFilterLibInit()* – initialize ip filter facility

**SYNOPSIS** `void ipFilterLibInit (void)`

**DESCRIPTION** This routine links the ip filter facility into the VxWorks system. These routines are included automatically if `INCLUDE_IP_FILTER` is defined in `configAll.h`.

**RETURNS** N/A

**SEE ALSO** `ipFilterLib`

---

## *ipstatShow()*

**NAME** *ipstatShow()* – display IP statistics

**SYNOPSIS**

```
void ipstatShow
(
 BOOL zero /* TRUE = reset statistics to 0 */
)
```

**DESCRIPTION** This routine displays detailed statistics for the IP protocol.

**RETURNS** N/A

**SEE ALSO** `netShow`

---

## *rint()*

|                      |                                                                                                                   |
|----------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>rint()</i> – convert a double-precision value to an integer                                                    |
| <b>SYNOPSIS</b>      | <pre>int rint (     double x /* argument */ )</pre>                                                               |
| <b>DESCRIPTION</b>   | This routine converts a double-precision value <i>x</i> to an integer using the selected IEEE rounding direction. |
| <b>CAVEAT</b>        | The rounding direction is not pre-selectable and is fixed for round-to-the-nearest.                               |
| <b>INCLUDE FILES</b> | <b>math.h</b>                                                                                                     |
| <b>RETURNS</b>       | The integer representation of <i>x</i> .                                                                          |
| <b>SEE ALSO</b>      | <b>mathALib</b>                                                                                                   |

---

## *rintf()*

|                      |                                                                                                                   |
|----------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>rintf()</i> – convert a single-precision value to an integer                                                   |
| <b>SYNOPSIS</b>      | <pre>int rintf (     float x /* argument */ )</pre>                                                               |
| <b>DESCRIPTION</b>   | This routine converts a single-precision value <i>x</i> to an integer using the selected IEEE rounding direction. |
| <b>CAVEAT</b>        | The rounding direction is not pre-selectable and is fixed as round-to-the-nearest.                                |
| <b>INCLUDE FILES</b> | <b>math.h</b>                                                                                                     |
| <b>RETURNS</b>       | The integer representation of <i>x</i> .                                                                          |
| <b>SEE ALSO</b>      | <b>mathALib</b>                                                                                                   |

---

## *iround()*

|                      |                                                                                     |
|----------------------|-------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>iround()</i> – round a number to the nearest integer                             |
| <b>SYNOPSIS</b>      | <pre>int iround (     double x /* argument */ )</pre>                               |
| <b>DESCRIPTION</b>   | This routine rounds a double-precision value <i>x</i> to the nearest integer value. |
| <b>NOTE</b>          | If <i>x</i> is spaced evenly between two integers, it returns the even integer.     |
| <b>INCLUDE FILES</b> | <b>math.h</b>                                                                       |
| <b>RETURNS</b>       | The integer nearest to <i>x</i> .                                                   |
| <b>SEE ALSO</b>      | <b>mathALib</b>                                                                     |

---

## *iroundf()*

|                      |                                                                                     |
|----------------------|-------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>iroundf()</i> – round a number to the nearest integer                            |
| <b>SYNOPSIS</b>      | <pre>int iroundf (     float x /* argument */ )</pre>                               |
| <b>DESCRIPTION</b>   | This routine rounds a single-precision value <i>x</i> to the nearest integer value. |
| <b>NOTE</b>          | If <i>x</i> is spaced evenly between two integers, the even integer is returned.    |
| <b>INCLUDE FILES</b> | <b>math.h</b>                                                                       |
| <b>RETURNS</b>       | The integer nearest to <i>x</i> .                                                   |
| <b>SEE ALSO</b>      | <b>mathALib</b>                                                                     |

## *isalnum()*

|                      |                                                                                                                 |
|----------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>isalnum()</i> – test whether a character is alphanumeric (ANSI)                                              |
| <b>SYNOPSIS</b>      | <pre>int isalnum (     int c /* character to test */ )</pre>                                                    |
| <b>DESCRIPTION</b>   | This routine tests whether <i>c</i> is a character for which <i>isalpha()</i> or <i>isdigit()</i> returns true. |
| <b>INCLUDE FILES</b> | <code>ctype.h</code>                                                                                            |
| <b>RETURNS</b>       | Non-zero if and only if <i>c</i> is alphanumeric.                                                               |
| <b>SEE ALSO</b>      | <code>ansiCtype</code>                                                                                          |

## *isalpha()*

|                      |                                                                                                                 |
|----------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>isalpha()</i> – test whether a character is a letter (ANSI)                                                  |
| <b>SYNOPSIS</b>      | <pre>int isalpha (     int c /* character to test */ )</pre>                                                    |
| <b>DESCRIPTION</b>   | This routine tests whether <i>c</i> is a character for which <i>isupper()</i> or <i>islower()</i> returns true. |
| <b>INCLUDE FILES</b> | <code>ctype.h</code>                                                                                            |
| <b>RETURNS</b>       | Non-zero if and only if <i>c</i> is a letter.                                                                   |
| <b>SEE ALSO</b>      | <code>ansiCtype</code>                                                                                          |

## *isatty()*

|                    |                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>isatty()</i> – return whether the underlying driver is a tty device                              |
| <b>SYNOPSIS</b>    | <pre>BOOL isatty (     int fd /* file descriptor to check */ )</pre>                                |
| <b>DESCRIPTION</b> | This routine simply invokes the <i>ioctl()</i> function FIOISATTY on the specified file descriptor. |
| <b>RETURNS</b>     | TRUE, or FALSE if the driver does not indicate a tty device.                                        |
| <b>SEE ALSO</b>    | ioLib                                                                                               |

---

## *iscntrl()*

|                      |                                                                           |
|----------------------|---------------------------------------------------------------------------|
| <b>NAME</b>          | <i>iscntrl()</i> – test whether a character is a control character (ANSI) |
| <b>SYNOPSIS</b>      | <pre>int iscntrl (     int c /* character to test */ )</pre>              |
| <b>DESCRIPTION</b>   | This routine tests whether <i>c</i> is a control character.               |
| <b>INCLUDE FILES</b> | ctype.h                                                                   |
| <b>RETURNS</b>       | Non-zero if and only if <i>c</i> is a control character.                  |
| <b>SEE ALSO</b>      | ansiCtype                                                                 |

## ***isdigit()***

|                      |                                                                       |
|----------------------|-----------------------------------------------------------------------|
| <b>NAME</b>          | <i>isdigit()</i> – test whether a character is a decimal digit (ANSI) |
| <b>SYNOPSIS</b>      | <pre>int isdigit (     int c /* character to test */ )</pre>          |
| <b>DESCRIPTION</b>   | This routine tests whether <i>c</i> is a decimal-digit character.     |
| <b>INCLUDE FILES</b> | <code>ctype.h</code>                                                  |
| <b>RETURNS</b>       | Non-zero if and only if <i>c</i> is a decimal digit.                  |
| <b>SEE ALSO</b>      | <code>ansiCtype</code>                                                |

## ***isgraph()***

|                      |                                                                                                                             |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>isgraph()</i> – test whether a character is a printing, non-white-space character (ANSI)                                 |
| <b>SYNOPSIS</b>      | <pre>int isgraph (     int c /* character to test */ )</pre>                                                                |
| <b>DESCRIPTION</b>   | This routine returns true if <i>c</i> is a printing character, and not a character for which <i>isspace()</i> returns true. |
| <b>INCLUDE FILES</b> | <code>ctype.h</code>                                                                                                        |
| <b>RETURNS</b>       | Non-zero if and only if <i>c</i> is a printable, non-white-space character.                                                 |
| <b>SEE ALSO</b>      | <code>ansiCtype</code> , <i>isspace()</i>                                                                                   |

---

## *islower()*

|                      |                                                                           |
|----------------------|---------------------------------------------------------------------------|
| <b>NAME</b>          | <i>islower()</i> – test whether a character is a lower-case letter (ANSI) |
| <b>SYNOPSIS</b>      | <pre>int islower (     int c /* character to test */ )</pre>              |
| <b>DESCRIPTION</b>   | This routine tests whether <i>c</i> is a lower-case letter.               |
| <b>INCLUDE FILES</b> | <code>ctype.h</code>                                                      |
| <b>RETURNS</b>       | Non-zero if and only if <i>c</i> is a lower-case letter.                  |
| <b>SEE ALSO</b>      | <code>ansiCtype</code>                                                    |

---

## *isprint()*

|                      |                                                                                                |
|----------------------|------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>isprint()</i> – test whether a character is printable, including the space character (ANSI) |
| <b>SYNOPSIS</b>      | <pre>int isprint (     int c /* character to test */ )</pre>                                   |
| <b>DESCRIPTION</b>   | This routine returns true if <i>c</i> is a printing character or the space character.          |
| <b>INCLUDE FILES</b> | <code>ctype.h</code>                                                                           |
| <b>RETURNS</b>       | Non-zero if and only if <i>c</i> is printable, including the space character.                  |
| <b>SEE ALSO</b>      | <code>ansiCtype</code>                                                                         |

## *ispunct()*

|                      |                                                                                                                                                    |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>ispunct()</i> – test whether a character is punctuation (ANSI)                                                                                  |
| <b>SYNOPSIS</b>      | <pre>int ispunct (     int c /* character to test */ )</pre>                                                                                       |
| <b>DESCRIPTION</b>   | This routine tests whether a character is punctuation, i.e., a printing character for which neither <i>isspace()</i> nor <i>isalnum()</i> is true. |
| <b>INCLUDE FILES</b> | <code>ctype.h</code>                                                                                                                               |
| <b>RETURNS</b>       | Non-zero if and only if <i>c</i> is a punctuation character.                                                                                       |

***kernelInit()***

---

***kernelInit()*****NAME** *kernelInit()* – initialize the kernel

**SYNOPSIS**

```
void kernelInit
(
 FUNCPTR rootRtn, /* user start-up routine */
 unsigned rootMemSize, /* memory for TCB and root stack */
 char * pMemPoolStart, /* beginning of memory pool */
 char * pMemPoolEnd, /* end of memory pool */
 unsigned intStackSize, /* interrupt stack size */
 int lockOutLevel /* interrupt lock-out level (1-7) */
)
```

**DESCRIPTION** This routine initializes and starts the kernel. It should be called only once. The parameter *rootRtn* specifies the entry point of the user's start-up code that subsequently initializes system facilities (i.e., the I/O system, network). Typically, *rootRtn* is set to *usrRoot()*.

Interrupts are enabled for the first time after *kernelInit()* exits. VxWorks will not exceed the specified interrupt lock-out level during any of its brief uses of interrupt locking as a means of mutual exclusion.

The system memory partition is initialized by *kernelInit()* with the size set by *pMemPoolStart* and *pMemPoolEnd*. Architectures that support a separate interrupt stack allocate a portion of memory for this purpose, of *intStackSize* bytes starting at *pMemPoolStart*.

**RETURNS** N/A**SEE ALSO** *kernelLib*, *intLockLevelSet()*

---

***kernelTimeSlice()*****NAME** *kernelTimeSlice()* – enable round-robin selection

**SYNOPSIS**

```
STATUS kernelTimeSlice
(
 int ticks /* time-slice in ticks or 0 to disable round-robin */
)
```

|                    |                                                                                                                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | This routine enables round-robin selection among tasks of same priority and sets the system time-slice to <i>ticks</i> . Round-robin scheduling is disabled by default. A time-slice of zero ticks disables round-robin scheduling. For more information about round-robin scheduling, see the manual entry for <b>kernelLib</b> . |
| <b>RETURNS</b>     | OK, always.                                                                                                                                                                                                                                                                                                                        |
| <b>SEE ALSO</b>    | <b>kernelLib</b>                                                                                                                                                                                                                                                                                                                   |

---

## *kernelVersion()*

|                    |                                                                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>kernelVersion()</i> – return the kernel revision string                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <code>char *kernelVersion (void)</code>                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | This routine returns a string which contains the current revision of the kernel. The string is of the form "WIND version x.y", where "x" corresponds to the kernel major revision, and "y" corresponds to the kernel minor revision. |
| <b>RETURNS</b>     | A pointer to a string of format "WIND version x.y".                                                                                                                                                                                  |
| <b>SEE ALSO</b>    | <b>kernelLib</b>                                                                                                                                                                                                                     |

---

## *kill()*

|                    |                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>kill()</i> – send a signal to a task (POSIX)                                                              |
| <b>SYNOPSIS</b>    | <pre>int kill (     int tid, /* task to send signal to */     int signo /* signal to send to task */ )</pre> |
| <b>DESCRIPTION</b> | This routine sends a signal <i>signo</i> to the task specified by <i>tid</i> .                               |
| <b>RETURNS</b>     | OK (0), or ERROR (-1) if the task ID or signal number is invalid.                                            |
| <b>ERRNO</b>       | EINVAL                                                                                                       |
| <b>SEE ALSO</b>    | <b>sigLib</b>                                                                                                |

**l()**

---

**l()****NAME** `l()` – disassemble and display a specified number of instructions

**SYNOPSIS**

```
void l
(
 INSTR * addr, /* address of first instruction to disassemble if 0, */
 /* from the last instruction disassembled on the */
 /* call to l */
 int count /* number of instruction to disassemble */
 /* if 0, use the same the last call to l */
)
```

**DESCRIPTION** This routine disassembles a specified number of instructions and displays them on standard output. If the address of an instruction is entered in the system symbol table, the symbol will be displayed as a label for that instruction. Also, addresses in the opcode field of instructions will be displayed symbolically.

To execute, enter:

```
-> l [address [,count]]
```

If *address* is omitted or zero, disassembly continues from the previous address. If *count* is omitted or zero, the last specified count is used (initially 10). As with all values entered via the shell, the address may be typed symbolically.

**RETURNS** N/A**SEE ALSO** `dbgLib`, *VxWorks Programmer's Guide: Target Shell*, `windsh`, *Tornado User's Guide: Shell*

---

**l0()****NAME** `l0()` – return the contents of register **I0** (also **I1** – **I7**) (SPARC)

**SYNOPSIS**

```
int l0
(
 int taskId /* task ID, 0 means default task */
)
```

**DESCRIPTION** This command extracts the contents of local register **I0** from the TCB of a specified task. If *taskId* is omitted or 0, the current default task is assumed.

Similar routines are provided for all local registers (10 – 17): *l0()* – *l7()*.

**RETURNS** The contents of register 10 (or the requested register).

**SEE ALSO** *dbgArchLib*, *VxWorks Programmer's Guide: Target Shell*

## *labs()*

**NAME** *labs()* – compute the absolute value of a **long** (ANSI)

**SYNOPSIS**

```
long labs
(
 long i /* long for which to return absolute value */
)
```

**DESCRIPTION** This routine computes the absolute value of a specified **long**. If the result cannot be represented, the behavior is undefined. This routine is equivalent to *abs()*, except that the argument and return value are all of type **long**.

**INCLUDE FILES** *stdlib.h*

**RETURNS** The absolute value of *i*.

**SEE ALSO** *ansiStdlib*

## *ld()*

**NAME** *ld()* – load an object module into memory

**SYNOPSIS**

```
MODULE_ID ld
(
 int syms, /* -1, 0, or 1 */
 BOOL noAbort, /* TRUE = don't abort script on error */
 char * name /* name of object module, NULL = standard input */
)
```

**DESCRIPTION** This command loads an object module from a file or from standard input. The object module must be in UNIX *a.out* format. External references in the module are resolved during loading. The *syms* parameter determines how symbols are loaded; possible values:

***ldexp()***

- 0 – Add global symbols to the system symbol table.
- 1 – Add global and local symbols to the system symbol table.
- 1 – Add no symbols to the system symbol table.

If there is an error during loading (e.g., externals undefined, too many symbols, etc.), then *shellScriptAbort()* is called to stop any script that this routine was called from. If *noAbort* is TRUE, errors are noted but ignored.

The normal way of using *ld()* is to load all symbols (*syms* = 1) during debugging and to load only global symbols later.

**EXAMPLE**

The following example loads the **a.out** file **module** from the default file device into memory, and adds any global symbols to the symbol table:

```
-> ld <module
```

This example loads **test.o** with all symbols:

```
-> ld 1,0,"test.o"
```

**RETURNS**

MODULE\_ID, or NULL if there are too many symbols, the object file format is invalid, or there is an error reading the file.

**SEE ALSO**

**usrLib**, **loadLib**, *VxWorks Programmer's Guide: Target Shell*, **windsh**, *Tornado User's Guide: Shell*

***ldexp()*****NAME**

*ldexp()* – multiply a number by an integral power of 2 (ANSI)

**SYNOPSIS**

```
double ldexp
(
 double v, /* a floating point number */
 int xexp /* exponent */
)
```

**DESCRIPTION**

This routine multiplies a floating-point number by an integral power of 2. A range error may occur.

**INCLUDE FILES**

**math.h**

**RETURNS**

The double-precision value of *v* times 2 to the power of *xexp*.

**SEE ALSO**

**ansiMath**

## **ledControl()**

|                    |                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>ledControl()</i> – change the line-editor ID parameters                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <pre>void ledControl (     int led_id, /* ID returned by ledOpen */     int inFd,   /* new input fd (NONE = no change) */     int outFd,  /* new output fd (NONE = no change) */     int histSize /* new history list size (NONE = no change), */                 /* (0 = display) */ )</pre> |
| <b>DESCRIPTION</b> | This routine changes the input/output file descriptor and the size of the history list.                                                                                                                                                                                                       |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                                           |
| <b>SEE ALSO</b>    | <i>ledLib</i>                                                                                                                                                                                                                                                                                 |

---

## *ledOpen()*

|                    |                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>ledOpen()</i> – create a new line-editor ID                                                                                                                                     |
| <b>SYNOPSIS</b>    | <pre>int ledOpen (     int inFd,    /* low-level device input fd */     int outFd,   /* low-level device output fd */     int histSize /* size of history list */ )</pre>          |
| <b>DESCRIPTION</b> | This routine creates the ID that is used by <i>ledRead()</i> , <i>ledClose()</i> , and <i>ledControl()</i> . Storage is allocated for up to <i>histSize</i> previously read lines. |
| <b>RETURNS</b>     | The line-editor ID, or ERROR if the routine runs out of memory.                                                                                                                    |
| <b>SEE ALSO</b>    | <i>ledLib</i> , <i>ledRead()</i> , <i>ledClose()</i> , <i>ledControl()</i>                                                                                                         |

---

## *ledRead()*

|                    |                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>ledRead()</i> – read a line with line-editing                                                                                                                                              |
| <b>SYNOPSIS</b>    | <pre>int ledRead (     int led_id, /* ID returned by ledOpen */     char * string, /* where to return line */     int maxBytes /* maximum number of chars to read */ )</pre>                  |
| <b>DESCRIPTION</b> | This routine handles line-editing and history substitutions. If the low-level input file descriptor is not in <i>OPT_LINE</i> mode, only an ordinary <i>read()</i> routine will be performed. |
| <b>RETURNS</b>     | The number of characters read, or EOF.                                                                                                                                                        |
| <b>SEE ALSO</b>    | <i>ledLib</i>                                                                                                                                                                                 |

---

## *lio\_listio()*

**NAME** *lio\_listio()* – initiate a list of asynchronous I/O requests (POSIX)

**SYNOPSIS**

```
int lio_listio
(
 int mode, /* LIO_WAIT or LIO_NOWAIT */
 struct aiocb * list[], /* list of operations */
 int nEnt, /* size of list */
 struct sigevent * pSig /* signal on completion */
)
```

**DESCRIPTION** This routine submits a number of I/O operations (up to `AIO_LISTIO_MAX`) to be performed asynchronously. *list* is a pointer to an array of `aiocb` structures that specify the AIO operations to be performed. The array is of size *nEnt*.

The `aiocb` structure specifies the AIO operation to be performed. Valid entries include `LIO_READ`, `LIO_WRITE`, and `LIO_NOP`. `LIO_READ` corresponds to a call to `aioread()`, `LIO_WRITE` corresponds to a call to `aiowrite()`, and `LIO_NOP` is ignored.

The *mode* argument can be either `LIO_WAIT` or `LIO_NOWAIT`. If *mode* is `LIO_WAIT`, `lio_listio()` does not return until all the AIO operations complete and the *pSig* argument is ignored. If *mode* is `LIO_NOWAIT`, the `lio_listio()` returns as soon as the operations are queued. In this case, if *pSig* is not NULL and the signal number indicated by `pSig>sigev_signo` is not zero, the signal `pSig>sigev_signo` is delivered when all requests have completed.

**RETURNS** OK if requests queued successfully, otherwise ERROR.

**ERRNO** EINVAL, EAGAIN, EIO

**INCLUDE FILES** aio.h

**SEE ALSO** aioPxLib, `aioread()`, `aiowrite()`, `aioreaderror()`, `aioreturn()`.

|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>listen()</i> – enable connections to a socket                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <pre>STATUS listen (     int s,          /* socket descriptor */     int backlog /* number of connections to queue */ )</pre>                                                                                                                                             |
| <b>DESCRIPTION</b> | This routine enables connections to a socket. It also specifies the maximum number of unaccepted connections that can be pending at one time ( <i>backlog</i> ). After enabling connections with <i>listen()</i> , connections are actually accepted by <i>accept()</i> . |
| <b>RETURNS</b>     | OK, or ERROR if the socket is invalid or unable to listen.                                                                                                                                                                                                                |
| <b>SEE ALSO</b>    | sockLib                                                                                                                                                                                                                                                                   |

| <b>SYNOPSIS</b>    | <pre>void lkup (     char * substr /* substring to match */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p>This command lists all symbols in the system symbol table whose names contain the string <i>substr</i>. If <i>substr</i> is omitted or is 0, a short summary of symbol table statistics is printed. If <i>substr</i> is the empty string (""), all symbols in the table are listed.</p> <p>This command also displays symbols that are local, i.e., symbols found in the system symbol table only because their module was loaded by <i>ld()</i>.</p> <p>By default, <i>lkup()</i> displays 22 symbols at a time. This can be changed by modifying the global variable <b>symLkupPgSz</b>. If this variable is set to 0, <i>lkup()</i> displays all the symbols without interruption.</p> |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>ll()</i> – do a long listing of directory contents                                                                                                                    |
| <b>SYNOPSIS</b>    | <pre>STATUS ll (     char * dirName /* name of directory to list */ )</pre>                                                                                              |
| <b>DESCRIPTION</b> | <p>This command causes a long listing of a directory's contents to be displayed. It is equivalent to:</p> <pre>-&gt; ls dirName, TRUE</pre>                              |
| <b>NOTE</b>        | When used with <b>netDrv</b> devices (FTP or RSH), <i>ll()</i> does not give directory information. It is equivalent to an <i>ls()</i> call with no long-listing option. |

**RETURNS** OK or ERROR.

## *ln97xEndLoad()*

**NAME** *ln97xEndLoad()* – initialize the driver and device

**SYNOPSIS**

```
END_OBJ * ln97xEndLoad
(
 char * initString /* string to be parse by the driver */
)
```

**DESCRIPTION** This routine initializes the driver and the device to the operational state. All of the device-specific parameters are passed in *initString*, which expects a string of the following format:

```
unit:devMemAddr:devIoAddr:pciMemBase:<vecnum:intLvl:memAdrs:memSize:memWidth:csr3b:
offset:flags
```

This routine can be called in two modes. If it is called with an empty but allocated string, it places the name of this device (that is, "lnPci") into the *initString* and returns 0.

If the string is allocated and not empty, the routine attempts to load the driver using the values specified in the string.

**RETURNS** An END object pointer, or NULL on error, or 0 and the name of the device if the *initString* was NULL.

**SEE ALSO** *ln97xEnd*

---

## *ln97xInitParse()*

**NAME** *ln97xInitParse()* – parse the initialization string

**SYNOPSIS**

```
STATUS ln97xInitParse
(
 LN_97X_DRV_CTRL * pDrvCtrl, /* pointer to the control structure */
 char * initString /* initialization string */
)
```

|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | <p>Parse the input string. This routine is called from <i>In97xEndLoad()</i> which initializes some values in the driver control structure with the values passed in the initialization string.</p> <p>The initialization string format is:<br/><i>unit:devMemAddr:devIoAddr:pciMemBase:&lt;vecNum:intLvl:memAdrs:memSize:memWidth:csr3b:offset:flags</i></p> <p><i>unit</i><br/>Device unit number, a small integer.</p> <p><i>devMemAddr</i><br/>Device register base memory address</p> <p><i>devIoAddr</i><br/>Device register base IO address</p> <p><i>pciMemBase</i><br/>Base address of PCI memory space</p> <p><i>vecNum</i><br/>Interrupt vector number.</p> <p><i>intLvl</i><br/>Interrupt level.</p> <p><i>memAdrs</i><br/>Memory pool address or NONE.</p> <p><i>memSize</i><br/>Memory pool size or zero.</p> <p><i>memWidth</i><br/>Memory system size, 1, 2, or 4 bytes (optional).</p> <p><i>CSR3</i><br/>Value of CSR3 (for endian-ness mainly)</p> <p><i>offset</i><br/>Offset of starting of data in the device buffers.</p> <p><i>flags</i><br/>Device specific flags, for future use.</p> |
| <b>RETURNS</b>     | OK, or ERROR if any arguments are invalid.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## ***lnattach()***

**NAME** *lnattach()* – publish the **In** network interface and initialize driver structures

**SYNOPSIS**

```
STATUS lnattach
(
 int unit, /* unit number */
 char * devAdrs, /* LANCE I/O address */
 int ivec, /* interrupt vector */
 int ilevel, /* interrupt level */
 char * memAdrs, /* address of memory pool (-1 = malloc it) */
 ULONG memSize, /* only used if memory pool is NOT malloc()'d */
 int memWidth, /* byte-width of data (-1 = any width) */
 int spare, /* not used */
 int spare2 /* not used */
)
```

**DESCRIPTION** This routine publishes the **In** interface by filling in a network interface record and adding this record to the system list. This routine also initializes the driver and the device to the operational state.

The *memAdrs* parameter can be used to specify the location of the memory that will be shared between the driver and the device. The value **NONE** is used to indicate that the driver should obtain the memory.

The *memSize* parameter is valid only if the *memAdrs* parameter is not set to **NONE**, in which case *memSize* indicates the size of the provided memory region.

The *memWidth* parameter sets the memory pool's data port width (in bytes); if it is **NONE**, any data width is used.

**BUGS** To zero out LANCE data structures, this routine uses *bzero()*, which ignores the *memWidth* specification and uses any size data access to write to memory.

**RETURNS** OK or ERROR.

**SEE ALSO** *if\_in*

**InPciattach()**

---

**InPciattach()**

**NAME** *InPciattach()* – publish the InPci network interface and initialize the driver and device

**SYNOPSIS**

```
STATUS InPciattach
(
 int unit, /* unit number */
 char * devAdrs, /* LANCE I/O address */
 int ivec, /* interrupt vector */
 int ilevel, /* interrupt level */
 char * memAdrs, /* address of memory pool (-1 = malloc it) */
 ULONG memSize, /* used if memory pool is NOT malloc()'d */
 int memWidth, /* byte-width of data (-1 = any width) */
 ULONG pciMemBase, /* memory base as seen from PCI */
 int spare2 /* not used */
)
```

**DESCRIPTION** This routine publishes the In interface by filling in a network interface record and adding this record to the system list. This routine also initializes the driver and the device to the operational state.

The *memAdrs* parameter can be used to specify the location of the memory that will be shared between the driver and the device. The value NONE is used to indicate that the driver should obtain the memory.

The *memSize* parameter is valid only if the *memAdrs* parameter is not set to NONE, in which case *memSize* indicates the size of the provided memory region.

The *memWidth* parameter sets the memory pool's data port width (in bytes); if it is NONE, any data width is used.

**BUGS** To zero out LANCE data structures, this routine uses *bzero()*, which ignores the *memWidth* specification and uses any size data access to write to memory.

**RETURNS** OK or ERROR.

## **loadModuleAt()**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>loadModuleAt()</i> – load an object module into memory                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <pre>MODULE_ID loadModuleAt (     int  fd,      /* fd from which to read module */     int  symFlag, /* symbols to add to table */                 /* (LOAD_[NO   LOCAL   GLOBAL   ALL]_SYMBOLS) */     char * *ppText, /* load text segment at addr pointed to by this ptr, */                 /* load addr via this ptr */     char * *ppData, /* load data segment at addr pointed to by this */                 /* return load addr via this ptr */     char * *ppBss  /* load BSS segment at addr pointed to by this ptr, */                 /* load addr via this ptr */ ) </pre> |
| <b>DESCRIPTION</b> | <p>This routine reads an object module from <i>fd</i>, and loads the code, data, and BSS segments at the specified load addresses in memory set aside by the user using <i>malloc()</i>, or in the</p>                                                                                                                                                                                                                                                                                                                                                                                  |

system memory partition as described below. The module is properly relocated according to the relocation commands in the file. Unresolved externals will be linked to symbols found in the system symbol table. Symbols in the module being loaded can optionally be added to the system symbol table.

#### LINKING UNRESOLVED EXTERNALS

As the module is loaded, any unresolved external references are resolved by looking up the missing symbols in the the system symbol table. If found, those references are correctly linked to the new module. If unresolved external references cannot be found in the system symbol table, then an error message ("undefined symbol: ...") is printed for the symbol, but the loading/linking continues. In this case, NULL will be returned after the module is loaded.

#### ADDING SYMBOLS TO THE SYMBOL TABLE

The symbols defined in the module to be loaded may be optionally added to the system symbol table, depending on the value of *symFlag*:

##### LOAD\_NO\_SYMBOLS

add no symbols to the system symbol table

##### LOAD\_LOCAL\_SYMBOLS

add only local symbols to the system symbol table

##### LOAD\_GLOBAL\_SYMBOLS

add only external symbols to the system symbol table

##### LOAD\_ALL\_SYMBOLS

add both local and external symbols to the system symbol table

##### HIDDEN\_MODULE

do not display the module via *moduleShow()*.

In addition, the following symbols are also added to the symbol table to indicate the start of each segment: *filename\_text*, *filename\_data*, and *filename\_bss*, where *filename* is the name associated with the fd.

#### RELOCATION

The relocation commands in the object module are used to relocate the text, data, and BSS segments of the module. The location of each segment can be specified explicitly, or left unspecified in which case memory will be allocated for the segment from the system memory partition. This is determined by the parameters *ppText*, *ppData*, and *ppBss*, each of which can have the following values:

##### NULL

no load address is specified, none will be returned;

##### A pointer to LD\_NO\_ADDRESS

no load address is specified, the return address is referenced by the pointer;

##### A pointer to an address

the load address is specified.

The *ppText*, *ppData*, and *ppBss* parameters specify where to load the text, data, and bss sections respectively. Each of these parameters is a pointer to a pointer; for example, **\*\*ppText** gives the address where the text segment is to begin.

For any of the three parameters, there are two ways to request that new memory be allocated, rather than specifying the section's starting address: you can either specify the parameter itself as `NULL`, or you can write the constant `LD_NO_ADDRESS` in place of an address. In the second case, **loadModuleAt()** routine replaces the `LD_NO_ADDRESS` value with the address actually used for each section (that is, it records the address at *\*ppText*, *\*ppData*, or *\*ppBss*).

The double indirection not only permits reporting the addresses actually used, but also allows you to specify loading a segment at the beginning of memory, since the following cases can be distinguished:

- (1) Allocate memory for a section (text in this example): *ppText* == `NULL`
- (2) Begin a section at address zero (the text section, below): *\*ppText* == `0`

Note that **loadModule()** is equivalent to this routine if all three of the segment-address parameters are set to `NULL`.

**COMMON**

Some host compiler/linker combinations internally use another storage class known as *common*. In the C language, uninitialized global variables are eventually put in the BSS segment. However, in partially linked object modules, they are flagged internally as common and the static linker (host) resolves these and places them in BSS as a final step in creating a fully linked object module. However, the VxWorks loader is most often used to load partially linked object modules. When the VxWorks loader encounters a variable labeled as common, memory for the variable is allocated, with **malloc()**, and the variable is entered in the system symbol table (if specified) at that address. Note that most UNIX loaders have an option that forces resolution of the common storage while leaving the module relocatable (e.g., with typical BSD UNIX loaders, use options **-rd**).

**EXAMPLES**

Load a module into allocated memory, but do not return segment addresses:

```
module_id = loadModuleAt (fd, LOAD_GLOBAL_SYMBOLS, NULL, NULL, NULL);
```

Load a module into allocated memory, and return segment addresses:

```
pText = pData = pBss = LD_NO_ADDRESS;
module_id = loadModuleAt (fd, LOAD_GLOBAL_SYMBOLS, &pText, &pData,
&pBss);
```

Load a module to off-board memory at a specified address:

```
pText = 0x800000; /* address of text segment */
pData = pBss = LD_NO_ADDRESS /* other segments follow by default */
module_id = loadModuleAt (fd, LOAD_GLOBAL_SYMBOLS, &pText, &pData,
&pBss);
```

## ***loattach()***

- RETURNS** `MODULE_ID`, or `NULL` if the file cannot be read, there is not enough memory, or the file format is illegal.
- SEE ALSO** `loadLib`, *VxWorks Programmer's Guide: Basic OS*

---

## ***loattach()***

- NAME** `loattach()` – publish the `lo` network interface and initialize the driver and pseudo-device
- SYNOPSIS** `STATUS loattach (void)`
- DESCRIPTION** This routine attaches an `lo` Ethernet interface to the network, if the interface exists. It makes the interface available by filling in the network interface record. The system initializes the interface when it is ready to accept packets.
- RETURNS** `OK`.
- SEE ALSO** `if_loop`

---

## ***localeconv()***

- NAME** `localeconv()` – set the components of an object with type `lconv` (ANSI)
- SYNOPSIS** `struct lconv *localeconv (void)`
- DESCRIPTION** This routine sets the components of an object with type `struct lconv` with values appropriate for the formatting of numeric quantities (monetary and otherwise) according to the rules of the current locale.
- The members of the structure with type `char *` are pointers to strings any of which (except `decimal_point`) can point to "" to indicate that the value is not available in the current locale or is of zero length. The members with type `char` are nonnegative numbers, any of which can be `CHAR_MAX` to indicate that the value is not available in the current locale. The members include the following:
- char \*decimal\_point**  
The decimal-point character used to format nonmonetary quantities.
- char \*thousands\_sep**  
The character used to separate groups of digits before the decimal-point character in

formatted nonmonetary quantities.

**char \*grouping**

A string whose elements indicate the size of each group of digits in formatted nonmonetary quantities.

**char \*int\_curr\_symbol**

The international currency symbol applicable to the current locale. The first three characters contain the alphabetic international currency symbol in accordance with those specified in ISO 4217:1987. The fourth character (immediately preceding the null character) is the character used to separate the international currency symbol from the monetary quantity.

**char \*currency\_symbol**

The local currency symbol applicable to the current locale.

**char \*mon\_decimal\_point**

The decimal-point used to format monetary quantities.

**char \*mon\_thousands\_sep**

The separator for groups of digits before the decimal-point in formatted monetary quantities.

**char \*mon\_grouping**

A string whose elements indicate the size of each group of digits in formatted monetary quantities.

**char \*positive\_sign**

The string used to indicate a nonnegative-valued formatted monetary quantity.

**char \*negative\_sign**

The string used to indicate a negative-valued formatted monetary quantity.

**char int\_frac\_digits**

The number of fractional digits (those after the decimal-point) to be displayed in an internationally formatted monetary quantity.

**char frac\_digits**

The number of fractional digits (those after the decimal-point) to be displayed in a formatted monetary quantity.

**char p\_cs\_precedes**

Set to 1 or 0 if the **currency\_symbol** respectively precedes or succeeds the value for a nonnegative formatted monetary quantity.

**char p\_sep\_by\_space**

Set to 1 or 0 if the **currency\_symbol** respectively is or is not separated by a space from the value for a nonnegative formatted monetary quantity.

**char n\_cs\_precedes**

Set to 1 or 0 if the **currency\_symbol** respectively precedes or succeeds the value for a negative formatted monetary quantity.

***localeconv()***

**char n\_sep\_by\_space**

Set to 1 or 0 if the **currency\_symbol** respectively is or is not separated by a space from the value for a negative formatted monetary quantity.

**char p\_sign\_posn**

Set to a value indicating the positioning of the **positive\_sign** for a nonnegative formatted monetary quantity.

**char n\_sign\_posn**

Set to a value indicating the positioning of the **negative\_sign** for a negative formatted monetary quantity.

The elements of **grouping** and **mon\_grouping** are interpreted according to the following:

**CHAR\_MAX**

No further grouping is to be performed.

0

The previous element is to be repeatedly used for the remainder of the digits.

other

The integer value is the number of the digits that comprise the current group. The next element is examined to determine the size of the next group of digits before the current group.

The values of **p\_sign\_posn** and **n\_sign\_posn** are interpreted according to the following:

0 Parentheses surround the quantity and **currency\_symbol**.

1 The sign string precedes the quantity and **currency\_symbol**.

2 The sign string succeeds the quantity and **currency\_symbol**.

3 The sign string immediately precedes the **currency\_symbol**.

4 The sign string immediately succeeds the **currency\_symbol**.

The implementation behaves as if no library function calls **localeconv()**.

The **localeconv()** routine returns a pointer to the filled-in object. The structure pointed to by the return value is not modified by the program, but may be overwritten by a subsequent call to **localeconv()**. In addition, calls to **setlocale()** with categories **LC\_ALL**, **LC\_MONETARY**, or **LC\_NUMERIC** may overwrite the contents of the structure.

**INCLUDE FILES**     **locale.h, limits.h**

**RETURNS**            A pointer to the structure **lconv**.

**SEE ALSO**            **ansiLocale**

## *log10f()*

**NAME** *log10f()* – compute a base-10 logarithm (ANSI)

**SYNOPSIS**

```
float log10f
(
 float x /* value to compute the base-10 logarithm of */
)
```

**DESCRIPTION** This routine returns the base-10 logarithm of *x* in single precision.

**INCLUDE FILES** **math.h**

**RETURNS** The single-precision base-10 logarithm of *x*.

**SEE ALSO** **mathALib**

---

## *logf()*

**NAME** *logf()* – compute a natural logarithm (ANSI)

**SYNOPSIS**

```
float logf
(
 float x /* value to compute the natural logarithm of */
)
```

**DESCRIPTION** This routine returns the logarithm of *x* in single precision.

**INCLUDE FILES** **math.h**

**RETURNS** The single-precision natural logarithm of *x*.

**SEE ALSO** **mathALib**

---

## *logFdAdd()*

|                    |                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>logFdAdd()</i> – add a logging file descriptor                                                                                                                               |
| <b>SYNOPSIS</b>    | <pre>STATUS logFdAdd (     int fd /* file descriptor for additional logging device */ )</pre>                                                                                   |
| <b>DESCRIPTION</b> | This routine adds to the log file descriptor list another file descriptor <i>fd</i> to which messages will be logged. The file descriptor must be a valid open file descriptor. |
| <b>RETURNS</b>     | OK, or ERROR if the allowable number of additional logging file descriptors (5) is exceeded.                                                                                    |
| <b>SEE ALSO</b>    | <i>logLib</i> , <i>logFdDelete()</i>                                                                                                                                            |

---

## *logFdDelete()*

|                    |                                                                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>logFdDelete()</i> – delete a logging file descriptor                                                                                                                                           |
| <b>SYNOPSIS</b>    | <pre>STATUS logFdDelete (     int fd /* file descriptor to stop using as logging device */ )</pre>                                                                                                |
| <b>DESCRIPTION</b> | This routine removes from the log file descriptor list a logging file descriptor added by <i>logFdAdd()</i> . The file descriptor is not closed; but is no longer used by the logging facilities. |
| <b>RETURNS</b>     | OK, or ERROR if the file descriptor was not added with <i>logFdAdd()</i> .                                                                                                                        |
| <b>SEE ALSO</b>    | <i>logLib</i> , <i>logFdAdd()</i>                                                                                                                                                                 |

**logFdSet()**

---

**logFdSet()**

**NAME** *logFdSet()* – set the primary logging file descriptor

**SYNOPSIS**

```
void logFdSet
(
 int fd /* file descriptor to use as logging device */
)
```

**DESCRIPTION** This routine changes the file descriptor where messages from *logMsg()* are written, allowing the log device to be changed from the default specified by *logInit()*. It first removes the old file descriptor (if one had been previously set) from the log file descriptor list, then adds the new *fd*.

The old logging file descriptor is not closed or affected by this call; it is simply no longer used by the logging facilities.

**RETURNS** N/A

**SEE ALSO** *logLib*, *logFdAdd()*, *logFdDelete()*

---

**loginDefaultEncrypt()**

**NAME** *loginDefaultEncrypt()* – default password encryption routine

**SYNOPSIS**

```
STATUS loginDefaultEncrypt
(
 char * in, /* input string */
 char * out /* encrypted string */
)
```

**DESCRIPTION** This routine provides default encryption for login passwords. It employs a simple encryption algorithm. It takes as arguments a string *in* and a pointer to a buffer *out*. The encrypted string is then stored in the buffer.

The input strings must be at least 8 characters and no more than 40 characters.

If a more sophisticated encryption algorithm is needed, this routine can be replaced, as long as the new encryption routine retains the same declarations as the default routine. The routine *vxencrypt* in *host/hostOs/bin* should also be replaced by a host version of *encryptionRoutine*. For more information, see the manual entry for *loginEncryptInstall()*.

**RETURNS** OK, or ERROR if the password is invalid.

**SEE ALSO** loginLib, loginEncryptInstall(), vxencrypt

---

## loginEncryptInstall()

**NAME** loginEncryptInstall() – install an encryption routine

**SYNOPSIS**

```
void loginEncryptInstall
(
 FUNCPTR rtn, /* function pointer to encryption routine */
 int var /* argument to the encryption routine (unused) */
)
```

**DESCRIPTION** This routine allows the user to install a custom encryption routine. The custom routine *rtn* must be of the following form:

```
STATUS encryptRoutine
(
 char *password, /* string to encrypt */
 char *encryptedPassword /* resulting encryption */
)
```

When a custom encryption routine is installed, a host version of this routine must be written to replace the tool vxencrypt in **host/hostOs/bin**.

**EXAMPLE** The custom example above could be installed as follows:

```
#ifdef INCLUDE_SECURITY
 loginInit (); /* initialize login table */
 shellLoginInstall (loginPrompt, NULL); /* install shell security */
 loginEncryptInstall (encryptRoutine, NULL); /* install encrypt routine */
#endif
```

**RETURNS** N/A

**SEE ALSO** loginLib, loginDefaultEncrypt(), vxencrypt

## *loginInit()*

|                    |                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>loginInit()</i> – initialize the login table                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <code>void loginInit (void)</code>                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | This routine must be called to initialize the login data structure used by routines throughout this module. If the configuration macro <b>INCLUDE_SECURITY</b> is defined, it is called by <i>usrRoot()</i> in <b>usrConfig.c</b> , before any other routines in this module. |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                           |
| <b>SEE ALSO</b>    | <b>loginLib</b>                                                                                                                                                                                                                                                               |

## *logInit()*

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>logInit()</i> – initialize message logging library                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <pre>STATUS logInit (     int fd,      /* file descriptor to use as logging device */     int maxMsgs /* max. number of messages allowed in log queue */ )</pre>                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | <p>This routine specifies the file descriptor to be used as the logging device and the number of messages that can be in the logging queue. If more than <i>maxMsgs</i> are in the queue, they will be discarded. A message is printed to indicate lost messages.</p> <p>This routine spawns <i>logTask()</i>, the task-level portion of error logging.</p> <p>This routine must be called before any other routine in <b>logLib</b>. This is done by the root task, <i>usrRoot()</i>, in <b>usrConfig.c</b>.</p> |
| <b>RETURNS</b>     | OK, or ERROR if a message queue could not be created or <i>logTask()</i> could not be spawned.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SEE ALSO</b>    | <b>logLib</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

---

## *loginPrompt()*

|                    |                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>loginPrompt()</i> – display a login prompt and validate a user entry                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <pre>STATUS loginPrompt (     char * userName /* user name, ask if NULL or not provided */ )</pre>                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | <p>This routine displays a login prompt and validates a user entry. If both user name and password match with an entry in the login table, the user is then given access to the VxWorks system. Otherwise, it prompts the user again.</p> <p>All control characters are disabled during authentication except CTRL-D, which will terminate the remote login session.</p> |
| <b>RETURNS</b>     | OK if the name and password are valid, or ERROR if there is an EOF or the routine times out.                                                                                                                                                                                                                                                                             |
| <b>SEE ALSO</b>    | <b>loginLib</b>                                                                                                                                                                                                                                                                                                                                                          |

---

## *loginStringSet()*

|                    |                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>loginStringSet()</i> – change the login string                                                              |
| <b>SYNOPSIS</b>    | <pre>void loginStringSet (     char * newString /* string to become new login prompt */ )</pre>                |
| <b>DESCRIPTION</b> | This routine changes the login prompt string to <i>newString</i> . The maximum string length is 80 characters. |
| <b>RETURNS</b>     | N/A                                                                                                            |
| <b>SEE ALSO</b>    | <b>loginLib</b>                                                                                                |

---

## *loginUserAdd()*

**NAME** *loginUserAdd()* – add a user to the login table

**SYNOPSIS**

```
STATUS loginUserAdd
(
 char name[MAX_LOGIN_NAME_LEN+1], /* user name */
 char passwd[80] /* user password */
)
```

**DESCRIPTION** This routine adds a user name and password entry to the login table. Note that what is saved in the login table is the user name and the address of *passwd*, not the actual password.

The length of user names should not exceed `MAX_LOGIN_NAME_LEN`, while the length of passwords depends on the encryption routine used. For the default encryption routine, passwords should be at least 8 characters long and no more than 40 characters.

The procedure for adding a new user to login table is as follows:

- (1) Generate the encrypted password by invoking `vxencrypt` in `host/hostOs/bin`.
- (2) Add a user by invoking `loginUserAdd()` in the VxWorks shell with the user name and the encrypted password.

The password of a user can be changed by first deleting the user entry, then adding the user entry again with the new encrypted password.

**EXAMPLE**

```
-> loginUserAdd "peter", "RRdRd9Qbyz"
value = 0 = 0x0
-> loginUserAdd "robin", "bSzydqbsb"
value = 0 = 0x0
-> loginUserShow
 User Name
 =====
 peter
 robin
value = 0 = 0x0
->
```

**RETURNS** OK, or ERROR if the user name has already been entered.

**SEE ALSO** `loginLib`, `vxencrypt`

---

## *loginUserDelete()*

**NAME** *loginUserDelete()* – delete a user entry from the login table

**SYNOPSIS** `STATUS loginUserDelete`

```
(
 char * name, /* user name */
 char * passwd /* user password */
)
```

**DESCRIPTION** This routine deletes an entry in the login table. Both the user name and password must be specified to remove an entry from the login table.

**RETURNS** OK, or ERROR if the specified user or password is incorrect.

**SEE ALSO** `loginLib`

---

## *loginUserShow()*

**NAME** *loginUserShow()* – display the user login table

**SYNOPSIS** `void loginUserShow (void)`

**DESCRIPTION** This routine displays valid user names.

**EXAMPLE**

```
-> loginUserShow ()
 User Name
 =====
 peter
 robin
 value = 0 = 0x0
```

**RETURNS** N/A

**SEE ALSO** `loginLib`

## *loginUserVerify()*

|                    |                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>loginUserVerify()</i> – verify a user name and password in the login table                                      |
| <b>SYNOPSIS</b>    | <pre>STATUS loginUserVerify (     char * name, /* name of user */     char * passwd /* password of user */ )</pre> |
| <b>DESCRIPTION</b> | This routine verifies a user entry in the login table.                                                             |
| <b>RETURNS</b>     | OK, or ERROR if the user name or password is not found.                                                            |
| <b>SEE ALSO</b>    | <i>loginLib</i>                                                                                                    |

---

## *logMsg()*

|                               |                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>                   | <i>logMsg()</i> – log a formatted error message                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>               | <pre>int logMsg (     char * fmt, /* format string for print */     int  arg1, /* first of six required args for fmt */     int  arg2,     int  arg3,     int  arg4,     int  arg5,     int  arg6 )</pre>                                                                                                                            |
| <b>DESCRIPTION</b>            | <p>This routine logs a specified message via the logging task. This routine's syntax is similar to <i>printf()</i> -- a format string is followed by arguments to format. However, the <i>logMsg()</i> routine requires a fixed number of arguments (6).</p> <p>The task ID of the caller is prepended to the specified message.</p> |
| <b>SPECIAL CONSIDERATIONS</b> | <p>Because <i>logMsg()</i> does not actually perform the output directly to the logging streams, but instead queues the message to the logging task, <i>logMsg()</i> can be called from interrupt service routines.</p>                                                                                                              |

However, since the arguments are interpreted by the *logTask()* at the time of actual logging, instead of at the moment when *logMsg()* is called, arguments to *logMsg()* should not be pointers to volatile entities (e.g., dynamic strings on the caller stack).

For more detailed information about the use of *logMsg()*, see the manual entry for **logLib**.

**EXAMPLE**

If the following code were executed by task 20:

```
{
 name = "GRONK";
 num = 123;
 logMsg ("ERROR - name = %s, num = %d.\n", name, num, 0, 0, 0, 0);
}
```

the following error message would appear on the system log:

```
0x180400 (t20): ERROR - name = GRONK, num = 123.
```

**RETURNS**

The number of bytes written to the log queue, or EOF if the routine is unable to write a message.

**logLib**, *printf()*, *logTask()*

---

## *logout()*

**NAME**

*logout()* – log out of the VxWorks system

**SYNOPSIS**

```
void logout (void)
```

**DESCRIPTION**

This command logs out of the VxWorks shell. If a remote login is active (via **rlogin** or **telnet**), it is stopped, and standard I/O is restored to the console.

**SEE ALSO**

**usrLib**, *rlogin()*, *telnet()*, *shellLogout()*, *VxWorks Programmer's Guide: Target Shell*

---

## *logTask()*

**NAME**

*logTask()* – message-logging support task

**SYNOPSIS**

```
void logTask (void)
```

**longjmp()**

|                    |                                                                                                                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | This routine prints the messages logged with <i>logMsg()</i> . It waits on a message queue and prints the messages as they arrive on the file descriptor specified by <i>logInit()</i> (or a subsequent call to <i>logFdSet()</i> or <i>logFdAdd()</i> ).<br><br>This task is spawned by <i>logInit()</i> . |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                                                         |

| <b>NAME</b>        | <i>longjmp()</i> – perform non-local goto by restoring saved environment (ANSI)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <pre>void longjmp (     jmp_buf env,     int     val )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>This routine restores the environment saved by the most recent invocation of the <i>setjmp()</i> routine that used the same <i>jmp_buf</i> specified in the argument <i>env</i>. The restored environment includes the program counter, thus transferring control to the <i>setjmp()</i> caller.</p> <p>If there was no corresponding <i>setjmp()</i> call, or if the function containing the corresponding <i>setjmp()</i> routine call has already returned, the behavior of <i>longjmp()</i> is unpredictable.</p> <p>All accessible objects in memory retain their values as of the time <i>longjmp()</i> was called, with one exception: local objects on the C stack that are not declared <b>volatile</b>, and have been changed between the <i>setjmp()</i> invocation and the <i>longjmp()</i> call, have unpredictable values.</p> <p>The <i>longjmp()</i> function executes correctly in contexts of signal handlers and any of their associated functions (but not from interrupt handlers).</p> |
| <b>WARNING</b>     | Do not use <i>longjmp()</i> or <i>setjmp()</i> from an ISR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>RETURNS</b>     | This routine does not return to its caller. Instead, it causes <i>setjmp()</i> to return <i>val</i> , unless <i>val</i> is 0; in that case <i>setjmp()</i> returns 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>lptDevCreate()</i> – create a device for an LPT port                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <pre>STATUS lptDevCreate (     char * name,    /* name to use for this device */     int   channel /* physical channel for this device (0 - 2) */ )</pre>                                                                                                                                |
| <b>DESCRIPTION</b> | <p>This routine creates a device for a specified LPT port. Each port to be used should have exactly one device associated with it by calling this routine.</p> <p>For instance, to create the device <i>/lpt/0</i>, the proper call would be:</p> <pre>lptDevCreate ("/lpt/0", 0);</pre> |
| <b>RETURNS</b>     | OK, or ERROR if the driver is not installed, the channel is invalid, or the device already exists.                                                                                                                                                                                       |
| <b>SEE ALSO</b>    | <i>lptDrv()</i>                                                                                                                                                                                                                                                                          |

| <b>NAME</b>        | <i>ls()</i> – list the contents of a directory                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <pre>STATUS ls (     char * dirName, /* name of dir to list */     BOOL doLong /* if TRUE, do long listing */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p>This command is similar to UNIX <i>ls</i>. It lists the contents of a directory in one of two formats. If <i>doLong</i> is FALSE, only the names of the files (or subdirectories) in the specified directory are displayed. If <i>doLong</i> is TRUE, then the file name, size, date, and time are displayed. For a long listing, any entries that describe subdirectories are also flagged with the label "DIR".</p> <p>The <i>dirName</i> parameter specifies which directory to list. If <i>dirName</i> is omitted or NULL, the current working directory is listed.</p> <p>Empty directory entries and dosFs volume label entries are not reported.</p> |
| <b>NOTE</b>        | When used with <b>netDrv</b> devices (FTP or RSH), <i>doLong</i> has no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>RETURNS</b>     | OK or ERROR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>NAME</b>        | <i>lseek()</i> – set a file read/write pointer                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <pre>int lseek (     int fd,      /* file descriptor */     long offset, /* new byte offset to seek to */     int whence  /* relative file position */ )</pre>                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>This routine sets the file read/write pointer of file <i>fd</i> to <i>offset</i>. The argument <i>whence</i>, which affects the file position pointer, has three values:</p> <p>SEEK_SET (0)           - set to <i>offset</i><br/>SEEK_CUR (1)           - set to current position plus <i>offset</i><br/>SEEK_END (2)           - set to the size of the file plus <i>offset</i></p> <p>This routine calls <i>ioctl()</i> with functions FIOWHERE, FIONREAD, and FIOSEEK.</p> |
| <b>RETURNS</b>     | The new offset from the beginning of the file, or ERROR.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SEE ALSO</b>    | <i>ioLib</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>NAME</b>        | <i>lsOld()</i> – list the contents of an RT-11 directory                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <pre>STATUS lsOld (     char * dirName /* device to list */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b> | <p>This command is the old version of <i>ls()</i>, which used the old-style <i>ioctl()</i> function FIODIRENTRY to get information about entries in a directory. Since VxWorks 5.0, a new version of <i>ls()</i>, which uses POSIX directory and file functions, has replaced the older routine.</p> <p>This version remains in the system to support certain drivers that do not currently support the POSIX directory and file functions. This includes <b>netDrv</b>, which provides the Remote Shell (RSH) and File Transfer Protocol (FTP) mode remote file access (although</p> |

## ***lstAdd()***

**nfsDrv**, which uses NFS, does support the directory calls). Also, the new **ls()** no longer reports empty directory entries on RT-11 disks (i.e., the entries that describe unallocated sections of an RT-11 disk).

If no directory name is specified, the current working directory is listed.

**RETURNS** OK, or ERROR if the directory cannot be opened.

**SEE ALSO** **usrLib**, **ls()**, *VxWorks Programmer's Guide: Target Shell*

---

## ***lstAdd()***

**NAME** *lstAdd()* – add a node to the end of a list

**SYNOPSIS**

```
void lstAdd
(
 LIST * pList, /* pointer to list descriptor */
 NODE * pNode /* pointer to node to be added */
)
```

**DESCRIPTION** This routine adds a specified node to the end of a specified list.

**RETURNS** N/A

**SEE ALSO** **lstLib**

---

## ***lstConcat()***

**NAME** *lstConcat()* – concatenate two lists

**SYNOPSIS**

```
void lstConcat
(
 LIST * pDstList, /* destination list */
 LIST * pAddList /* list to be added to dstList */
)
```

**DESCRIPTION** This routine concatenates the second list to the end of the first list. The second list is left empty. Either list (or both) can be empty at the beginning of the operation.

**RETURNS** N/A

**SEE ALSO** `lstLib`

---

## *lstCount()*

**NAME** *lstCount()* – report the number of nodes in a list

**SYNOPSIS**

```
int lstCount
(
 LIST * pList /* pointer to list descriptor */
)
```

**DESCRIPTION** This routine returns the number of nodes in a specified list.

**RETURNS** The number of nodes in the list.

**SEE ALSO** `lstLib`

---

## *lstDelete()*

**NAME** *lstDelete()* – delete a specified node from a list

**SYNOPSIS**

```
void lstDelete
(
 LIST * pList, /* pointer to list descriptor */
 NODE * pNode /* pointer to node to be deleted */
)
```

**DESCRIPTION** This routine deletes a specified node from a specified list.

**RETURNS** N/A

**SEE ALSO** `lstLib`

## ***lstExtract()***

**NAME** *lstExtract()* – extract a sublist from a list

**SYNOPSIS**

```
void lstExtract
(
 LIST * pSrcList, /* pointer to source list */
 NODE * pStartNode, /* first node in sublist to be extracted */
 NODE * pEndNode, /* last node in sublist to be extracted */
 LIST * pDstList /* ptr to list where to put extracted list */
)
```

**DESCRIPTION** This routine extracts the sublist that starts with *pStartNode* and ends with *pEndNode* from a source list. It places the extracted list in *pDstList*.

**RETURNS** N/A

**SEE ALSO** *lstLib*

---

## ***lstFind()***

**NAME** *lstFind()* – find a node in a list

**SYNOPSIS**

```
int lstFind
(
 LIST * pList, /* list in which to search */
 NODE * pNode /* pointer to node to search for */
)
```

**DESCRIPTION** This routine returns the node number of a specified node (the first node is 1).

**RETURNS** The node number, or ERROR if the node is not found.

**SEE ALSO** *lstLib*

---

## *lstFirst()*

**NAME** *lstFirst()* – find first node in list

**SYNOPSIS**

```
NODE *lstFirst
(
 LIST * pList /* pointer to list descriptor */
)
```

**DESCRIPTION** This routine finds the first node in a linked list.

**RETURNS** A pointer to the first node in a list, or NULL if the list is empty.

**SEE ALSO** *lstLib*

---

## *lstFree()*

**NAME** *lstFree()* – free up a list

**SYNOPSIS**

```
void lstFree
(
 LIST * pList /* list for which to free all nodes */
)
```

**DESCRIPTION** This routine turns any list into an empty list. It also frees up memory used for nodes.

**RETURNS** N/A

**SEE ALSO** *lstLib*, *free()*

***lstGet()***

---

***lstGet()***

**NAME** *lstGet()* – delete and return the first node from a list

**SYNOPSIS**

```
NODE *lstGet
(
 LIST * pList /* ptr to list from which to get node */
)
```

**DESCRIPTION** This routine gets the first node from a specified list, deletes the node from the list, and returns a pointer to the node gotten.

**RETURNS** A pointer to the node gotten, or NULL if the list is empty.

**SEE ALSO** **lstLib**

---

***lstInit()***

**NAME** *lstInit()* – initialize a list descriptor

**SYNOPSIS**

```
void lstInit
(
 LIST * pList /* ptr to list descriptor to be initialized */
)
```

**DESCRIPTION** This routine initializes a specified list to an empty list.

**RETURNS** N/A

**SEE ALSO** **lstLib**

---

## *lstInsert()*

|                    |                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>lstInsert()</i> – insert a node in a list after a specified node                                                                                                                                   |
| <b>SYNOPSIS</b>    | <pre>void lstInsert (     LIST * pList, /* pointer to list descriptor */     NODE * pPrev, /* pointer to node after which to insert */     NODE * pNode  /* pointer to node to be inserted */ )</pre> |
| <b>DESCRIPTION</b> | This routine inserts a specified node in a specified list. The new node is placed following the list node <i>pPrev</i> . If <i>pPrev</i> is NULL, the node is inserted at the head of the list.       |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                   |
| <b>SEE ALSO</b>    | <i>lstLib</i>                                                                                                                                                                                         |

---

## *lstLast()*

|                    |                                                                                |
|--------------------|--------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>lstLast()</i> – find the last node in a list                                |
| <b>SYNOPSIS</b>    | <pre>NODE *lstLast (     LIST * pList /* pointer to list descriptor */ )</pre> |
| <b>DESCRIPTION</b> | This routine finds the last node in a list.                                    |
| <b>RETURNS</b>     | A pointer to the last node in the list, or NULL if the list is empty.          |
| <b>SEE ALSO</b>    | <i>lstLib</i>                                                                  |

***lstNext()***

---

***lstNext()***

|                    |                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>lstNext()</i> – find the next node in a list                                                  |
| <b>SYNOPSIS</b>    | <pre> NODE *lstNext (     NODE * pNode /* ptr to node whose successor is to be found */ ) </pre> |
| <b>DESCRIPTION</b> | This routine locates the node immediately following a specified node.                            |
| <b>RETURNS</b>     | A pointer to the next node in the list, or NULL if there is no next node.                        |
| <b>SEE ALSO</b>    | lstLib                                                                                           |

---

***lstNStep()***

|                    |                                                                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>lstNStep()</i> – find a list node <i>nStep</i> steps away from a specified node                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <pre> NODE *lstNStep (     NODE * pNode, /* the known node */     int   nStep /* number of steps away to find */ ) </pre>                                                                                                                                                |
| <b>DESCRIPTION</b> | This routine locates the node <i>nStep</i> steps away in either direction from a specified node. If <i>nStep</i> is positive, it steps toward the tail. If <i>nStep</i> is negative, it steps toward the head. If the number of steps is out of range, NULL is returned. |
| <b>RETURNS</b>     | A pointer to the node <i>nStep</i> steps away, or NULL if the node is out of range.                                                                                                                                                                                      |

|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>lstNth()</i> – find the Nth node in a list                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <pre>NODE *lstNth (     LIST * pList, /* pointer to list descriptor */     int   nodenum /* number of node to be found */ )</pre>                                                                                                                                                                         |
| <b>DESCRIPTION</b> | This routine returns a pointer to the node specified by a number <i>nodenum</i> where the first node in the list is numbered 1. Note that the search is optimized by searching forward from the beginning if the node is closer to the head, and searching back from the end if it is closer to the tail. |
| <b>RETURNS</b>     | A pointer to the Nth node, or NULL if there is no Nth node.                                                                                                                                                                                                                                               |
| <b>SEE ALSO</b>    | <i>lstLib</i>                                                                                                                                                                                                                                                                                             |

---

## *lstPrevious()*

|                    |                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>lstPrevious()</i> – find the previous node in a list                                              |
| <b>SYNOPSIS</b>    | <pre>NODE *lstPrevious (     NODE * pNode /* ptr to node whose predecessor is to be found */ )</pre> |
| <b>DESCRIPTION</b> | This routine locates the node immediately preceding the node pointed to by <i>pNode</i> .            |
| <b>RETURNS</b>     | A pointer to the previous node in the list, or NULL if there is no previous node.                    |
| <b>SEE ALSO</b>    | <i>lstLib</i>                                                                                        |

***m()***

---

***m()*****NAME** *m()* – modify memory**SYNOPSIS**  

```
void m
(
 void * adrs, /* address to change */
 int width /* width of unit to be modified (1, 2, 4, 8) */
)
```

**DESCRIPTION** This command prompts the user for modifications to memory in byte, short word, or long word specified by *width*, starting at the specified address. It prints each address and the current contents of that address, in turn. If *adrs* or *width* is zero or absent, it defaults to the previous value. The user can respond in one of several ways:**RETURN**

Do not change this address, but continue, prompting at the next address.

*number*Set the content of this address to *number*.

## . (dot)

Do not change this address, and quit.

## EOF

Do not change this address, and quit.

All numbers entered and displayed are in hexadecimal.

**RETURNS** N/A**SEE ALSO** *usrLib*, *mRegs()*, *VxWorks Programmer's Guide: Target Shell*, *windsh*, *Tornado User's Guide: Shell*

---

***m2Delete()*****NAME** *m2Delete()* – delete all the MIB-II library groups**SYNOPSIS** `STATUS m2Delete (void)`**DESCRIPTION** This routine cleans up the state associated with the MIB-II library.**RETURNS** OK (always).

**SEE ALSO** *m2Lib*, *m2SysDelete()*, *m2TcpDelete()*, *m2UdpDelete()*, *m2IcmpDelete()*, *m2IfDelete()*, *m2IpDelete()*

---

## *m2IcmpDelete()*

**NAME** *m2IcmpDelete()* – delete all resources used to access the ICMP group

**SYNOPSIS** `STATUS m2IcmpDelete (void)`

**DESCRIPTION** This routine frees all the resources allocated at the time the ICMP group was initialized. The ICMP group should not be accessed after this routine has been called.

**RETURNS** OK, always.

**SEE ALSO** *m2IcmpLib*, *m2IcmpInit()*, *m2IcmpGroupInfoGet()*

---

## *m2IcmpGroupInfoGet()*

**NAME** *m2IcmpGroupInfoGet()* – get the MIB-II ICMP-group global variables

**SYNOPSIS** `STATUS m2IcmpGroupInfoGet  
(  
    M2_ICMP * pIcmpInfo /* pointer to the ICMP group structure */  
)`

**DESCRIPTION** This routine fills in the ICMP structure at *pIcmpInfo* with the MIB-II ICMP scalar variables.

**RETURNS** OK, or ERROR if the input parameter *pIcmpInfo* is invalid.

**ERRNO** `S_m2Lib_INVALID_PARAMETER`

**SEE ALSO** *m2IcmpLib*, *m2IcmpInit()*, *m2IcmpDelete()*

***m2IcmpInit()***

---

***m2IcmpInit()***

**NAME** *m2IcmpInit()* – initialize MIB-II ICMP-group access

**SYNOPSIS** `STATUS m2IcmpInit (void)`

**DESCRIPTION** This routine allocates the resources needed to allow access to the MIB-II ICMP-group variables. This routine must be called before any ICMP variables can be accessed.

**RETURNS** OK, always.

**SEE ALSO** *m2IcmpLib*, *m2IcmpGroupInfoGet()*, *m2IcmpDelete()*

---

***m2IfDelete()***

**NAME** *m2IfDelete()* – delete all resources used to access the interface group

**SYNOPSIS** `STATUS m2IfDelete (void)`

**DESCRIPTION** This routine frees all the resources allocated at the time the group was initialized. The interface group should not be accessed after this routine has been called.

**RETURNS** OK, always.

**SEE ALSO** *m2IfLib*, *m2IfInit()*, *m2IfGroupInfoGet()*, *m2IfTblEntryGet()*, *m2IfTblEntrySet()*

---

***m2IfGroupInfoGet()***

**NAME** *m2IfGroupInfoGet()* – get the MIB-II interface-group scalar variables

**SYNOPSIS** `STATUS m2IfGroupInfoGet  
(  
    M2_INTERFACE * pIfInfo /* pointer to interface group structure */  
)`

**DESCRIPTION** This routine fills out the interface-group structure at *pIfInfo* with the values of MIB-II interface-group global variables.

**RETURNS** OK, or ERROR if *pIfInfo* is not a valid pointer.

**ERRNO** S\_m2Lib\_INVALID\_PARAMETER

**SEE ALSO** m2IfLib, m2IfInit(), m2IfTblEntryGet(), m2IfTblEntrySet(), m2IfDelete()

---

## ***m2IfInit()***

**NAME** *m2IfInit()* – initialize MIB-II interface-group routines

**SYNOPSIS**

```
STATUS m2IfInit
(
 FUNCPTR pTrapRtn, /* pointer to user trap generator */
 void * pTrapArg /* pointer to user trap generator argument */
)
```

**DESCRIPTION** This routine allocates the resources needed to allow access to the MIB-II interface-group variables. This routine must be called before any interface variables can be accessed. The input parameter *pTrapRtn* is an optional pointer to a user-supplied SNMP trap generator. The input parameter *pTrapArg* is an optional argument to the trap generator. Only one trap generator is supported.

**RETURNS** OK, always.

**ERRNO** S\_m2Lib\_CANT\_CREATE\_IF\_SEM

**SEE ALSO** m2IfLib, m2IfGroupInfoGet(), m2IfTblEntryGet(), m2IfTblEntrySet(), m2IfDelete()

---

## ***m2IfTblEntryGet()***

**NAME** *m2IfTblEntryGet()* – get a MIB-II interface-group table entry

**SYNOPSIS**

```
STATUS m2IfTblEntryGet
(
 int search, /* M2_EXACT_VALUE or M2_NEXT_VALUE */
 M2_INTERFACETBL * pIfReqEntry /* pointer to requested interface entry */
)
```

**m2IfTblEntrySet()**

|                    |                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | This routine maps the MIB-II interface index to the system's internal interface index. The <i>search</i> parameter is set to either <b>M2_EXACT_VALUE</b> or <b>M2_NEXT_VALUE</b> ; for a discussion of its use, see the manual entry for <b>m2Lib</b> . If the status of the interface has changed since it was last read, the user trap routine is called. |
| <b>RETURNS</b>     | OK, or ERROR if the input parameter is not specified, or a match is not found.                                                                                                                                                                                                                                                                               |
| <b>ERRNO</b>       | <b>S_m2Lib_INVALID_PARAMETER</b><br><b>S_m2Lib_ENTRY_NOT_FOUND</b>                                                                                                                                                                                                                                                                                           |
| <b>SEE ALSO</b>    | <b>m2IfLib</b> , <b>m2Lib</b> , <b>m2IfInit()</b> , <b>m2IfGroupInfoGet()</b> , <b>m2IfTblEntrySet()</b> , <b>m2IfDelete()</b>                                                                                                                                                                                                                               |

---

## **m2IfTblEntrySet()**

|                    |                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <b>m2IfTblEntrySet()</b> – set the state of a MIB-II interface entry to UP or DOWN                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <pre> STATUS m2IfTblEntrySet (     M2_INTERFACETBL * pIfTblEntry /* pointer to requested entry to change */ ) </pre>                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | This routine selects the interface specified in the input parameter <i>pIfTblEntry</i> and sets the interface to the requested state. It is the responsibility of the calling routine to set the interface index, and to make sure that the state specified in the <b>ifAdminStatus</b> field of the structure at <i>pIfTblEntry</i> is a valid MIB-II state, up(1) or down(2). |
| <b>RETURNS</b>     | OK, or ERROR if the input parameter is not specified, an interface is no longer valid, the interface index is incorrect, or the <i>ioctl()</i> command to the interface fails.                                                                                                                                                                                                  |
| <b>ERRNO</b>       | <b>S_m2Lib_INVALID_PARAMETER</b><br><b>S_m2Lib_ENTRY_NOT_FOUND</b><br><b>S_m2Lib_IF_CNFG_CHANGED</b>                                                                                                                                                                                                                                                                            |
| <b>SEE ALSO</b>    | <b>m2IfLib</b> , <b>m2IfInit()</b> , <b>m2IfGroupInfoGet()</b> , <b>m2IfTblEntryGet()</b> , <b>m2IfDelete()</b>                                                                                                                                                                                                                                                                 |

## *m2Init()*

**NAME** *m2Init()* – initialize the SNMP MIB-2 library

**SYNOPSIS**

```
STATUS m2Init
(
 char * pMib2SysDescr, /* sysDescr */
 char * pMib2SysContact, /* sysContact */
 char * pMib2SysLocation, /* sysLocation */
 M2_OBJECTID * pMib2SysObjectId, /* sysObjectID */
 FUNCPTR pTrapRtn, /* link up/down -trap routine */
 void * pTrapArg, /* trap routine arg */
 int maxRouteTableSize /* max size of routing table */
)
```

**DESCRIPTION** This routine initializes the MIB-2 library by calling the initialization routines for each MIB-2 group. The parameters *pMib2SysDescr*, *pMib2SysContact*, *pMib2SysLocation*, and *pMib2SysObjectId* are passed directly to *m2SysInit()*; *pTrapRtn* and *pTrapArg* are passed directly to *m2IfInit()*; and *maxRouteTableSize* is passed to *m2IpInit()*.

**RETURNS** OK if successful, otherwise ERROR.

**SEE ALSO** *m2Lib*, *m2SysInit()*, *m2TcpInit()*, *m2UdpInit()*, *m2IcmpInit()*, *m2IfInit()*, *m2IpInit()*

---

## *m2IpAddrTblEntryGet()*

**NAME** *m2IpAddrTblEntryGet()* – get an IP MIB-II address entry

**SYNOPSIS**

```
STATUS m2IpAddrTblEntryGet
(
 int search, /* M2_EXACT_VALUE or M2_NEXT_VALUE */
 M2_IPADDR * pIpAddrTblEntry /* ptr to requested IP address entry */
)
```

**DESCRIPTION** This routine traverses the IP address table and does an *M2\_EXACT\_VALUE* or a *M2\_NEXT\_VALUE* search based on the *search* parameter. The calling routine is responsible for supplying a valid MIB-II entry index in the input structure *pIpAddrTblEntry*. The index is the local IP address. The first entry in the table is retrieved by doing a NEXT search with the index field set to zero.

**RETURNS** OK, ERROR if the input parameter is not specified, or a match is not found.

**ERRNO** S\_m2Lib\_INVALID\_PARAMETER  
S\_m2Lib\_ENTRY\_NOT\_FOUND

**SEE ALSO** m2IpLib, m2Lib, m2IpInit(), m2IpGroupInfoGet(), m2IpGroupInfoSet(),  
m2IpAtransTblEntrySet(), m2IpRouteTblEntryGet(), m2IpRouteTblEntrySet(),  
m2IpDelete()

---

## **m2IpAtransTblEntryGet()**

**NAME** m2IpAtransTblEntryGet() – get a MIB-II ARP table entry

**SYNOPSIS**

```
STATUS m2IpAtransTblEntryGet
(
 int search, /* M2_EXACT_VALUE or M2_NEXT_VALUE */
 M2_IPATRANSTBL * pReqIpAtEntry /* ptr to the requested ARP entry */
)
```

**DESCRIPTION** This routine traverses the ARP table and does an M2\_EXACT\_VALUE or a M2\_NEXT\_VALUE search based on the *search* parameter. The calling routine is responsible for supplying a valid MIB-II entry index in the input structure *pReqIpAtEntry*. The index is made up of the network interface index and the IP address corresponding to the physical address. The first entry in the table is retrieved by doing a NEXT search with the index fields set to zero.

**RETURNS** OK, ERROR if the input parameter is not specified, or a match is not found.

**ERRNO** S\_m2Lib\_INVALID\_PARAMETER  
S\_m2Lib\_ENTRY\_NOT\_FOUND

**SEE ALSO** m2IpLib, m2Lib, m2IpInit(), m2IpGroupInfoGet(), m2IpGroupInfoSet(),  
m2IpAtransTblEntrySet(), m2IpRouteTblEntryGet(), m2IpRouteTblEntrySet(),  
m2IpDelete()

## *m2IpAtransTblEntrySet()*

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>m2IpAtransTblEntrySet()</i> – add, modify, or delete a MIB-II ARP entry                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <pre>STATUS m2IpAtransTblEntrySet (     M2_IPATRANSTBL * pReqIpAtEntry /* pointer to MIB-II ARP entry */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | This routine traverses the ARP table for the entry specified in the parameter <i>pReqIpAtEntry</i> . An ARP entry can be added, modified, or deleted. A MIB-II entry index is specified by the destination IP address and the physical media address. A new ARP entry can be added by specifying all the fields in the parameter <i>pReqIpAtEntry</i> . An entry can be modified by specifying the MIB-II index and the field that is to be modified. An entry is deleted by specifying the index and setting the type field in the input parameter <i>pReqIpAtEntry</i> to the MIB-II value "invalid" (2). |
| <b>RETURNS</b>     | OK, or ERROR if the input parameter is not specified, the physical address is not specified for an add/modify request, or the <i>ioctl()</i> request to the ARP module fails.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>ERRNO</b>       | S_m2Lib_INVALID_PARAMETER<br>S_m2Lib_ARP_PHYSADDR_NOT_SPECIFIED                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## ***m2IpGroupInfoGet()***

**NAME** *m2IpGroupInfoGet()* – get the MIB-II IP-group scalar variables

**SYNOPSIS**

```
STATUS m2IpGroupInfoGet
(
 M2_IP * pIpInfo /* pointer to IP MIB-II global group variables */
)
```

**DESCRIPTION** This routine fills in the IP structure at *pIpInfo* with the values of MIB-II IP global variables.

**RETURNS** OK, or ERROR if *pIpInfo* is not a valid pointer.

**ERRNO** S\_m2Lib\_INVALID\_PARAMETER

**SEE ALSO** *m2IpLib*, *m2IpInit()*, *m2IpGroupInfoSet()*, *m2IpAddrTblEntryGet()*,  
*m2IpAtransTblEntrySet()*, *m2IpRouteTblEntryGet()*, *m2IpRouteTblEntrySet()*,  
*m2IpDelete()*

---

## ***m2IpGroupInfoSet()***

**NAME** *m2IpGroupInfoSet()* – set MIB-II IP-group variables to new values

**SYNOPSIS**

```
STATUS m2IpGroupInfoSet
(
 unsigned int varToSet, /* bit field used to set variables */
 M2_IP * pIpInfo /* ptr to the MIB-II IP group global variables */
)
```

**DESCRIPTION** This routine sets one or more variables in the IP group, as specified in the input structure *pIpInfo* and the bit field parameter *varToSet*.

**RETURNS** OK, or ERROR if *pIpInfo* is not a valid pointer, or *varToSet* has an invalid bit field.

**ERRNO** S\_m2Lib\_INVALID\_PARAMETER  
 S\_m2Lib\_INVALID\_VAR\_TO\_SET

**SEE ALSO** m2IpLib, m2IpInit(), m2IpGroupInfoGet(), m2IpAddrTblEntryGet(),  
 m2IpAtransTblEntrySet(), m2IpRouteTblEntryGet(), m2IpRouteTblEntrySet(),  
 m2IpDelete()

## ***m2IpInit()***

**NAME** m2IpInit() – initialize MIB-II IP-group access

**SYNOPSIS** STATUS m2IpInit  
 (  
     int maxRouteTableSize /\* max size of routing table \*/  
 )

**DESCRIPTION** This routine allocates the resources needed to allow access to the MIB-II IP variables. This routine must be called before any IP variables can be accessed. The parameter *maxRouteTableSize* is used to increase the default size of the MIB-II route table cache.

**RETURNS** OK, or ERROR if the route table or the route semaphore cannot be allocated.

**ERRNO** S\_m2Lib\_CANT\_CREATE\_ROUTE\_SEM

**SEE ALSO** m2IpLib, m2IpGroupInfoGet(), m2IpGroupInfoSet(), m2IpAddrTblEntryGet(),  
 m2IpAtransTblEntrySet(), m2IpRouteTblEntryGet(), m2IpRouteTblEntrySet(),  
 m2IpDelete()

## ***m2IpRouteTblEntryGet()***

**NAME** m2IpRouteTblEntryGet() – get a MIB-2 routing table entry

**SYNOPSIS** STATUS m2IpRouteTblEntryGet  
 (  
     int search, /\* M2\_EXACT\_VALUE or M2\_NEXT\_VALUE \*/  
     M2\_IPROUTETBL \* pIpRouteTblEntry /\* route table entry \*/  
 )

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | <p>This routine retrieves MIB-II information about an entry in the network routing table and returns it in the caller-supplied structure <i>pIpRouteTblEntry</i>.</p> <p>The routine compares routing table entries to the address specified by the <b>ipRouteDest</b> member of the <i>pIpRouteTblEntry</i> structure, and retrieves an entry chosen by the <i>search</i> type (<b>M2_EXACT_VALUE</b> or <b>M2_NEXT_VALUE</b>, as described in the manual entry for <b>m2Lib</b>).</p> |
| <b>RETURNS</b>     | OK if successful, otherwise ERROR.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>NAME</b>        | <b>m2IpRouteTblEntrySet()</b> – set a MIB-II routing table entry                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <pre>STATUS m2IpRouteTblEntrySet (     int          varToSet,          /* variable to set */     M2_IPROUTETBL * pIpRouteTblEntry /* route table entry */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>This routine adds, changes, or deletes a network routing table entry. The table entry to be modified is specified by the <b>ipRouteDest</b> and <b>ipRouteNextHop</b> members of the <i>pIpRouteTblEntry</i> structure.</p> <p>The <i>varToSet</i> parameter is a bit-field mask that specifies which values in the route table entry are to be set.</p> <p>If <i>varToSet</i> has the <b>M2_IP_ROUTE_TYPE</b> bit set and <b>ipRouteType</b> has the value of <b>M2_ROUTE_TYPE_INVALID</b>, then the the routing table entry is deleted.</p> <p>If <i>varToSet</i> has the either the <b>M2_IP_ROUTE_DEST</b> or <b>M2_IP_ROUTE_NEXT_HOP</b> bit set, then either a new route entry is added to the table or an existing route entry is changed.</p> |
| <b>RETURNS</b>     | OK if successful, otherwise ERROR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## *m2OspfAreaEntryGet()*

**NAME** *m2OspfAreaEntryGet()* – get an entry from the OSPF area table (OSPF Opt.)

**SYNOPSIS**

```
STATUS m2OspfAreaEntryGet
(
 int searchType, /* M2_EXACT_VALUE or M2_NEXT_VALUE */
 M2_OSPF_AREA_ENTRY * pInfo /* ptr to area entry */
)
```

**DESCRIPTION** The structure pointed to by *pInfo* is filled with the contents of the area entry specified by *pInfo>ospfAreaId* and *searchType*.

**RETURNS** OK or ERROR.

**SEE ALSO** *ospfLib*

---

## *m2OspfAreaEntrySet()*

**NAME** *m2OspfAreaEntrySet()* – set values in an OSPF area entry (OSPF Opt.)

**SYNOPSIS**

```
STATUS m2OspfAreaEntrySet
(
 int varsToSet, /* flags specifying vars to set */
 M2_OSPF_AREA_ENTRY * pInfo /* ptr to area entry */
)
```

**DESCRIPTION** The area entry specified by *pInfo>ospfAreaId* will be updated with the values provided by *pInfo*. The *varsToSet* parameter indicates the fields to set and is a bitwise or of one or more of *M2\_OSPF\_AREA\_ID*, *M2\_OSPF\_AUTH\_TYPE*, and *M2\_OSPF\_IMPORT\_AS\_EXTERN*.

Note that the backbone area (0.0.0.0) is always present and does not need to be created explicitly. It is an error to use the *M2\_OSPF\_AREA\_ID* or *M2\_OSPF\_IMPORT\_AS\_EXTERN* flags with an area ID of 0.0.0.0.

**RETURNS** OK or ERROR.

**SEE ALSO** *ospfLib*

---

## ***m2OspfAreaRangeEntryGet()***

**NAME** *m2OspfAreaRangeEntryGet()* – get an OSPF area range entry (OSPF Opt.)

**SYNOPSIS**

```
STATUS m2OspfAreaRangeEntryGet
(
 int searchType, /* M2_EXACT_VALUE */
 /* or M2_NEXT_VALUE */
 M2_OSPF_AREA_RANGE_ENTRY * pInfo /* ptr to area arange entry */
)
```

**DESCRIPTION** The structure pointed to by *pInfo* is filled in with the OSPF area range entry specified by **pInfo>ospfAreaRangeAreaID**, **pInfo>ospfAreaRangeNet**, and *searchType*.

**RETURNS** OK or ERROR.

**SEE ALSO** **ospfLib**

---

## ***m2OspfAreaRangeEntrySet()***

**NAME** *m2OspfAreaRangeEntrySet()* – set values in an OSPF area range entry (OSPF Opt.)

**SYNOPSIS**

```
STATUS m2OspfAreaRangeEntrySet
(
 int varsToSet, /* flags specifying vars to set */
 M2_OSPF_AREA_RANGE_ENTRY * pInfo /* ptr to area range entry */
)
```

**DESCRIPTION** The OSPF area range entry specified by **pInfo>ospfAreaRangeAreaID** and **pInfo>ospfAreaRangeNet** is updated with the values provided in *pInfo*. The *varsToSet* parameter specifies the fields to set and is a bitwise or of one or more of **M2\_OSPF\_AREA\_RANGE\_AREA\_ID**, **M2\_OSPF\_AREA\_RANGE\_NET**, **M2\_OSPF\_AREA\_RANGE\_MASK**, and **M2\_OSPF\_AREA\_RANGE\_STATUS**.

**RETURNS** OK or ERROR.

**SEE ALSO** **ospfLib**

---

## *m2OspfGeneralGroupGet()*

**NAME** *m2OspfGeneralGroupGet()* – get values of OSPF general group objects (OSPF Opt.)

**SYNOPSIS**

```
STATUS m2OspfGeneralGroupGet
(
 M2_OSPF_GENERAL_GROUP * pInfo /* pointer to general group struct */
)
```

**DESCRIPTION** This routine fills in the structure pointed to by *pInfo* with the MIB-II values for the OSPF general group.

**RETURNS** OK, or ERROR if the get request fails.

**SEE ALSO** *ospfLib*

---

## *m2OspfGeneralGroupSet()*

**NAME** *m2OspfGeneralGroupSet()* – set values of OSPF general group objects (OSPF Opt.)

**SYNOPSIS**

```
STATUS m2OspfGeneralGroupSet
(
 int varsToSet, /* flags specifying vars to set */
 M2_OSPF_GENERAL_GROUP * pInfo /* ptr to general group structure */
)
```

**DESCRIPTION** This routine sets the values of the OSPF general group objects. The variables to set are specified by a bitwise or of one or more of the flags *M2\_OSPF\_ROUTER\_ID*, *M2\_OSPF\_ADMIN\_STAT*, *M2\_OSPF\_AS\_BDR\_RTR\_STATUS*, and *M2\_OSPF\_TOS\_SUPPORT*, in the *varsToSet* parameter.

**RETURNS** OK or ERROR.

**SEE ALSO** *ospfLib*

---

## ***m2OspfHostEntryGet()***

**NAME** *m2OspfHostEntryGet()* – get an OSPF host entry (OSPF Opt.)

**SYNOPSIS**

```
STATUS m2OspfHostEntryGet
(
 int searchType, /* M2_EXACT_VALUE or M2_NEXT_VALUE */
 M2_OSPF_HOST_ENTRY * pInfo /* ptr to host entry */
)
```

**DESCRIPTION** The structure pointed to by *pInfo* is filled in with the entry specified by *pInfo>ospfHostIpAddress*, *pInfo>ospfHostTOS*, and *searchType*.

**RETURNS** OK or ERROR.

**SEE ALSO** *ospfLib*

---

## ***m2OspfHostEntrySet()***

**NAME** *m2OspfHostEntrySet()* – set values in an OSPF host entry (OSPF Opt.)

**SYNOPSIS**

```
STATUS m2OspfHostEntrySet
(
 int varsToSet, /* flags specifying vars to set */
 M2_OSPF_HOST_ENTRY * pInfo /* ptr to host entry */
)
```

**DESCRIPTION** The OSPF host entry specified by *pInfo>ospfHostIpAddress* and *pInfo>ospfHostTOS* is updated with the values provided in *pInfo*. The *varsToSet* parameter indicates the fields to be set and is a bitwise or of one or more of *M2\_OSPF\_HOST\_IP\_ADDRESS*, *M2\_OSPF\_HOST\_TOS*, *M2\_OSPF\_HOST\_METRIC*, and *M2\_OSPF\_HOST\_STATUS*.

**RETURNS** OK or ERROR.

**SEE ALSO** *ospfLib*

## ***m2OspfIfMetricEntryGet()***

**NAME** *m2OspfIfMetricEntryGet()* – get an OSPF interface metric entry (OSPF Opt.)

**SYNOPSIS**

```
STATUS m2OspfIfMetricEntryGet
(
 int searchType, /* M2_EXACT_VALUE */
 /* or M2_NEXT_VALUE */
 M2_OSPF_IF_METRIC_ENTRY * pInfo /* ptr to interface metric entry */
)
```

**DESCRIPTION** The structure pointed to by *pInfo* is filled in with the entry specified by **pInfo>ospfIfMetricIpAddress**, **pInfo>ospfIfMetricAddressLessIf**, **pInfo>ospfIfMetricTOS**, and *searchType*.

**RETURNS** OK or ERROR.

**SEE ALSO** **ospfLib**

---

## ***m2OspfIfMetricEntrySet()***

**NAME** *m2OspfIfMetricEntrySet()* – set OSPF interface metric entry values (OSPF Opt.)

**SYNOPSIS**

```
STATUS m2OspfIfMetricEntrySet
(
 int varsToSet, /* flags specifying vars to set */
 M2_OSPF_IF_METRIC_ENTRY * pInfo /* ptr to interface metric entry */
)
```

**DESCRIPTION** The fields of the OSPF interface metric entry specified by **pInfo>ospfIfMetricIpAddress**, **pInfo>ospfIfMetricAddress**, and **pInfo>ospfIfMetricTOS** is updated with the contents of *pInfo*. The *varsToSet* parameter indicates the fields to set and is a bitwise or of one or more of **M2\_OSPF\_IF\_METRIC\_METRIC** or **M2\_OSPF\_IF\_METRIC\_STATUS**.

**RETURNS** OK or ERROR.

**SEE ALSO** **ospfLib**

---

## *m2OspfLsdbEntryGet()*

**NAME** *m2OspfLsdbEntryGet()* – get an OSPF link state database entry (OSPF Opt.)

**SYNOPSIS**

```
STATUS m2OspfLsdbEntryGet
(
 int searchType, /* M2_EXACT_VALUE or M2_NEXT_VALUE */
 M2_OSPF_LSDB_ENTRY * pInfo /* link state database entry */
)
```

**DESCRIPTION** The structure pointed to by *pInfo* is filled in with the entry specified by *pInfo>ospfLsdbAreaId*, *pInfo>ospfLsdbType*, and *searchType*.

**RETURNS** OK or ERROR.

**SEE ALSO** *ospfLib*

---

## *m2OspfNbrEntryGet()*

**NAME** *m2OspfNbrEntryGet()* – get an OSPF neighbor entry (OSPF Opt.)

**SYNOPSIS**

```
STATUS m2OspfNbrEntryGet
(
 int searchType, /* M2_EXACT_VALUE or M2_NEXT_VALUE */
 M2_OSPF_NBR_ENTRY * pInfo /* ptr to neighbor entry */
)
```

**DESCRIPTION** The structure pointed to by *pInfo* is filled in with the contents of the OSPF neighbor entry specified by *pInfo>ospfNbrIpAddr*, *pInfo>ospfNbrAddressLessIndex* and *searchType*.

**RETURNS** OK or ERROR.

**SEE ALSO** *ospfLib*

---

## ***m2OspfNbrEntrySet()***

**NAME** *m2OspfNbrEntrySet()* – set values in an OSPF neighbor entry (OSPF Opt.)

**SYNOPSIS**

```
STATUS m2OspfNbrEntrySet
(
 int varsToSet, /* flags specifying vars to set */
 M2_OSPF_NBR_ENTRY * pInfo /* ptr to neighbor entry */
)
```

**DESCRIPTION** The OSPF neighbor entry specified by **pInfo>ospfNbrIpAddr** and **pInfo>ospfNbrAddressLessIndex** is updated with the contents of *pInfo*. The *varsToSet* parameter indicates the fields to set, which can be **M2\_OSPF\_NBMA\_NBR\_STATUS**.

**RETURNS** OK or ERROR.

**SEE ALSO** **ospfLib**

---

## ***m2OspfStubAreaEntryGet()***

**NAME** *m2OspfStubAreaEntryGet()* – get an OSPF stub area entry (OSPF Opt.)

**SYNOPSIS**

```
STATUS m2OspfStubAreaEntryGet
(
 int searchType, /* M2_EXACT_VALUE */
 /* or M2_NEXT_VALUE */
 M2_OSPF_STUB_AREA_ENTRY * pInfo /* ptr to stub area entry */
)
```

**DESCRIPTION** The structure pointed to by *pInfo* is filled with the contents of the stub area entry specified by **pInfo>ospfStubAreaID**, **pInfo>ospfStubTOS** and *searchType*.

**RETURNS** OK or ERROR.

**SEE ALSO** **ospfLib**

---

## *m2OspfStubAreaEntrySet()*

**NAME** *m2OspfStubAreaEntrySet()* – set values in an OSPF stub area entry (OSPF Opt.)

**SYNOPSIS**

```
STATUS m2OspfStubAreaEntrySet
(
 int varsToSet, /* flags specifying vars to set */
 M2_OSPF_STUB_AREA_ENTRY * pInfo /* ptr to stub area entry */
)
```

**DESCRIPTION** The stub area entry specified by **pInfo>ospfStubAreaID** and **pInfo>ospfStubTOS** is updated with the values provided in *pInfo*. The *varsToSet* parameter indicates the fields to be modified and is a bitwise or of one or more of **M2\_OSPF\_STUB\_AREA\_ID**, **M2\_OSPF\_STUB\_TOS**, **M2\_OSPF\_STUB\_METRIC**, and **M2\_OSPF\_STUB\_STATUS**.

**RETURNS** OK or ERROR.

**SEE ALSO** **ospfLib**

---

## *m2OspfVirtIfEntryGet()*

**NAME** *m2OspfVirtIfEntryGet()* – get an OSPF virtual interface entry (OSPF Opt.)

**SYNOPSIS**

```
STATUS m2OspfVirtIfEntryGet
(
 int searchType, /* M2_EXACT_VALUE or M2_NEXT_VALUE */
 M2_OSPF_VIRT_IF_ENTRY * pInfo /* ptr to virtual interface entry */
)
```

**DESCRIPTION** The structure pointed to by *pInfo* is filled in with the contents of the OSPF virtual interface entry specified by **pInfo>ospfVirtIfAreaID**, **pInfo>ospfVirtIfNeighbor** and *searchType*.

**RETURNS** OK or ERROR.

**SEE ALSO** **ospfLib**

---

## *m2OspfVirtIfEntrySet()*

- NAME** *m2OspfVirtIfEntrySet()* – set OSPF virtual interface entry values (OSPF Opt.)
- SYNOPSIS**
- ```
STATUS m2OspfVirtIfEntrySet
(
    int                varsToSet, /* flags specifying vars to set */
    M2_OSPF_VIRT_IF_ENTRY * pInfo /* ptr to virtual interface entry */
)
```
- DESCRIPTION**
- The OSPF virtual interface entry specified by **pInfo>ospfVirtIfAreaID** and **pInfo>ospfVirtIfNeighbor** is updated with the contents of *pInfo*. The *varsToSet* parameter indicates the fields to be modified and is a bitwise or of one or more of:
- M2_OSPF_VIRT_IF_AREA_ID
 - M2_OSPF_VIRT_IF_NEIGHBOR
 - M2_OSPF_VIRT_IF_TRANSIT_DELAY
 - M2_OSPF_VIRT_IF_HELLO_INTERVAL
 - M2_OSPF_VIRT_IF_RTR_DEAD_INTERVAL
 - M2_OSPF_VIRT_IF_STATUS
 - M2_OSPF_VIRT_IF_AUTH_KEY
- RETURNS** OK or ERROR.
- SEE ALSO** *ospfLib*

m2OspfVirtNbrEntryGet()

- NAME** *m2OspfVirtNbrEntryGet()* – get an OSPF virtual neighbor entry (OSPF Opt.)
- SYNOPSIS**
- ```
STATUS m2OspfVirtNbrEntryGet
(
 int searchType, /* M2_EXACT_VALUE */
 /* or M2_NEXT_VALUE */
 M2_OSPF_VIRT_NBR_ENTRY * pInfo /* ptr to virtual neighbor entry */
)
```
- DESCRIPTION**
- The structure pointed to by *pInfo* is filled in with the contents of the OSPF virtual neighbor entry specified by **pInfo>ospfVirtNbrArea**, **pInfo>ospfVirtNbrRtrId**, and *searchType*.

**RETURNS** OK or ERROR.

**SEE ALSO** `ospfLib`

---

## *m2SysDelete()*

**NAME** *m2SysDelete()* – delete resources used to access the MIB-II system group

**SYNOPSIS** `STATUS m2SysDelete (void)`

**DESCRIPTION** This routine frees all the resources allocated at the time the group was initialized. Do not access the system group after calling this routine.

**RETURNS** OK, always.

**SEE ALSO** `m2SysLib`, `m2SysInit()`, `m2SysGroupInfoGet()`, `m2SysGroupInfoSet()`.

---

## *m2SysGroupInfoGet()*

**NAME** *m2SysGroupInfoGet()* – get system-group MIB-II variables

**SYNOPSIS** `STATUS m2SysGroupInfoGet`  
(  
    *M2\_SYSTEM* \* *pSysInfo* /\* pointer to MIB-II system group structure \*/  
)

**DESCRIPTION** This routine fills in the structure at *pSysInfo* with the values of MIB-II system-group variables.

**RETURNS** OK, or ERROR if *pSysInfo* is not a valid pointer.

**ERRNO** `S_m2Lib_INVALID_PARAMETER`

**SEE ALSO** `m2SysLib`, `m2SysInit()`, `m2SysGroupInfoSet()`, `m2SysDelete()`

---

## ***m2SysGroupInfoSet()***

- NAME** *m2SysGroupInfoSet()* – set system-group MIB-II variables to new values
- SYNOPSIS**
- ```
STATUS m2SysGroupInfoSet
(
    unsigned int varToSet, /* bit field of variables to set */
    M2_SYSTEM * pSysInfo /* pointer to the system structure */
)
```
- DESCRIPTION** This routine sets one or more variables in the system group as specified in the input structure at *pSysInfo* and the bit field parameter *varToSet*.
- RETURNS** OK, or ERROR if *pSysInfo* is not a valid pointer, or *varToSet* has an invalid bit field.
- ERRNO** S_m2Lib_INVALID_PARAMETER
S_m2Lib_INVALID_VAR_TO_SET
- SEE ALSO** *m2SysLib*, *m2SysInit()*, *m2SysGroupInfoGet()*, *m2SysDelete()*

m2SysInit()

- NAME** *m2SysInit()* – initialize MIB-II system-group routines
- SYNOPSIS**
- ```
STATUS m2SysInit
(
 char * pMib2SysDescr, /* pointer to MIB-2 sysDescr */
 char * pMib2SysContact, /* pointer to MIB-2 sysContact */
 char * pMib2SysLocation, /* pointer to MIB-2 sysLocation */
 M2_OBJECTID * pObjectId /* pointer to MIB-2 ObjectId */
)
```
- DESCRIPTION** This routine allocates the resources needed to allow access to the system-group MIB-II variables. This routine must be called before any system-group variables can be accessed. The input parameters *pMib2SysDescr*, *pMib2SysContact*, *pMib2SysLocation*, and *pObjectId* are optional. The parameters *pMib2SysDescr*, *pObjectId* are read only, as specified by MIB-II, and can be set only by this routine.
- RETURNS** OK, always.

ERRNO `S_m2Lib_CANT_CREATE_SYS_SEM`

SEE ALSO `m2SysLib`, `m2SysGroupInfoGet()`, `m2SysGroupInfoSet()`, `m2SysDelete()`

## *m2TcpConnEntryGet()*

NAME *m2TcpConnEntryGet()* – get a MIB-II TCP connection table entry

SYNOPSIS

```
STATUS m2TcpConnEntryGet
(
 int search, /* M2_EXACT_VALUE or M2_NEXT_VALUE */
 M2_TCPCONNTBL * pReqTcpConnEntry /* input = Index, Output = Entry */
)
```

DESCRIPTION This routine traverses the TCP table of users and does an `M2_EXACT_VALUE` or a `M2_NEXT_VALUE` search based on the *search* parameter (see `m2Lib`). The calling routine is responsible for supplying a valid MIB-II entry index in the input structure *pReqTcpConnEntry*. The index is made up of the local IP address, the local port number, the remote IP address, and the remote port. The first entry in the table is retrieved by doing a `M2_NEXT_VALUE` search with the index fields set to zero.

RETURNS OK, or ERROR if the input parameter is not specified or a match is not found.

ERRNO `S_m2Lib_INVALID_PARAMETER`  
`S_m2Lib_ENTRY_NOT_FOUND`

SEE ALSO `m2TcpLib`, `m2Lib`, `m2TcpInit()`, `m2TcpGroupInfoGet()`, `m2TcpConnEntrySet()`, `m2TcpDelete()`

---

## *m2TcpConnEntrySet()*

NAME *m2TcpConnEntrySet()* – set a TCP connection to the closed state

SYNOPSIS

```
STATUS m2TcpConnEntrySet
(
 M2_TCPCONNTBL * pReqTcpConnEntry /* pointer to TCP connection to close */
)
```

***m2TcpDelete()***

- DESCRIPTION** This routine traverses the TCP connection table and searches for the connection specified by the input parameter *pReqTcpConnEntry*. The calling routine is responsible for providing a valid index as the input parameter *pReqTcpConnEntry*. The index is made up of the local IP address, the local port number, the remote IP address, and the remote port. This call can only succeed if the connection is in the MIB-II state "deleteTCB" (12). If a match is found, the socket associated with the TCP connection is closed.
- RETURNS** OK, or ERROR if the input parameter is invalid, the state of the connection specified at *pReqTcpConnEntry* is not "closed," the specified connection is not found, a socket is not associated with the connection, or the *close()* call fails.
- SEE ALSO** *m2TcpLib*, *m2TcpInit()*, *m2TcpGroupInfoGet()*, *m2TcpConnEntryGet()*, *m2TcpDelete()*

***m2TcpDelete()***

- NAME** *m2TcpDelete()* – delete all resources used to access the TCP group
- SYNOPSIS** `STATUS m2TcpDelete (void)`
- DESCRIPTION** This routine frees all the resources allocated at the time the group was initialized. The TCP group should not be accessed after this routine has been called.
- RETURNS** OK, always.
- SEE ALSO** *m2TcpLib*, *m2TcpInit()*, *m2TcpGroupInfoGet()*, *m2TcpConnEntryGet()*, *m2TcpConnEntrySet()*

***m2TcpGroupInfoGet()***

- NAME** *m2TcpGroupInfoGet()* – get MIB-II TCP-group scalar variables
- SYNOPSIS** `STATUS m2TcpGroupInfoGet  
(  
    M2_TCPIINFO * pTcpInfo /* pointer to the TCP group structure */  
)`
- DESCRIPTION** This routine fills in the TCP structure pointed to by *pTcpInfo* with the values of MIB-II TCP-group scalar variables.

**RETURNS** OK, or ERROR if *pTcpInfo* is not a valid pointer.

**ERRNO** S\_m2Lib\_INVALID\_PARAMETER

**SEE ALSO** m2TcpLib, m2TcpInit(), m2TcpConnEntryGet(), m2TcpConnEntrySet(), m2TcpDelete()

---

## ***m2TcpInit()***

**NAME** *m2TcpInit()* – initialize MIB-II TCP-group access

**SYNOPSIS** STATUS m2TcpInit (void)

**DESCRIPTION** This routine allocates the resources needed to allow access to the TCP MIB-II variables. This routine must be called before any TCP variables can be accessed.

**RETURNS** OK, always.

**SEE ALSO** m2TcpLib, m2TcpGroupInfoGet(), m2TcpConnEntryGet(), m2TcpConnEntrySet(), m2TcpDelete()

---

## ***m2UdpDelete()***

**NAME** *m2UdpDelete()* – delete all resources used to access the UDP group

**SYNOPSIS** STATUS m2UdpDelete (void)

**DESCRIPTION** This routine frees all the resources allocated at the time the group was initialized. The UDP group should not be accessed after this routine has been called.

**RETURNS** OK, always.

**SEE ALSO** m2UdpLib, m2UdpInit(), m2UdpGroupInfoGet(), m2UdpTblEntryGet()

---

## ***m2UdpGroupInfoGet()***

**NAME** *m2UdpGroupInfoGet()* – get MIB-II UDP-group scalar variables

**SYNOPSIS**

```
STATUS m2UdpGroupInfoGet
(
 M2_UDP * pUdpInfo /* pointer to the UDP group structure */
)
```

**DESCRIPTION** This routine fills in the UDP structure at *pUdpInfo* with the MIB-II UDP scalar variables.

**RETURNS** OK, or ERROR if *pUdpInfo* is not a valid pointer.

**ERRNO** S\_m2Lib\_INVALID\_PARAMETER

**SEE ALSO** *m2UdpLib*, *m2UdpInit()*, *m2UdpTblEntryGet()*, *m2UdpDelete()*

---

## ***m2UdpInit()***

**NAME** *m2UdpInit()* – initialize MIB-II UDP-group access

**SYNOPSIS**

```
STATUS m2UdpInit (void)
```

**DESCRIPTION** This routine allocates the resources needed to allow access to the UDP MIB-II variables. This routine must be called before any UDP variables can be accessed.

**RETURNS** OK, always.

**SEE ALSO** *m2UdpLib*, *m2UdpGroupInfoGet()*, *m2UdpTblEntryGet()*, *m2UdpDelete()*

---

## ***m2UdpTblEntryGet()***

**NAME** *m2UdpTblEntryGet()* – get a UDP MIB-II entry from the UDP list of listeners

**SYNOPSIS**

```
STATUS m2UdpTblEntryGet
(
 int search, /* M2_EXACT_VALUE or M2_NEXT_VALUE */
```

```
M2_UDPTBL * pUdpEntry /* ptr to the requested entry with index */
)
```

**DESCRIPTION** This routine traverses the UDP table of listeners and does an **M2\_EXACT\_VALUE** or a **M2\_NEXT\_VALUE** search based on the *search* parameter. The calling routine is responsible for supplying a valid MIB-II entry index in the input structure *pUdpEntry*. The index is made up of the IP address and the local port number. The first entry in the table is retrieved by doing a **M2\_NEXT\_VALUE** search with the index fields set to zero.

**RETURNS** OK, or ERROR if the input parameter is not specified or a match is not found.

**ERRNO** S\_m2Lib\_INVALID\_PARAMETER  
S\_m2Lib\_ENTRY\_NOT\_FOUND

**SEE ALSO** m2UdpLib, m2Lib, m2UdpInit(), m2UdpGroupInfoGet(), m2UdpDelete()

## ***m68302SioInit()***

**NAME** *m68302SioInit()* – initialize a **M68302\_CP**

**SYNOPSIS**

```
void m68302SioInit
(
 M68302_CP * pCp
)
```

**DESCRIPTION** This routine initializes the driver function pointers and then resets the chip to a quiescent state. The BSP must already have initialized all the device addresses and the **baudFreq** fields in the **M68302\_CP** structure before passing it to this routine. The routine resets the device and initializes everything to support polled mode (if possible), but does not enable interrupts.

**RETURNS** N/A

**SEE ALSO** **m68302Sio**

## ***m68302SioInit2()***

## *m68332Int()*

**NAME** *m68332Int()* – handle an SCC interrupt

**SYNOPSIS**

```
void m68332Int
(
 M68332_CHAN * pChan
)
```

**DESCRIPTION** This routine handles SCC interrupts.

**RETURNS** N/A

**SEE ALSO** *m68332Sio*

---

## *m68360DevInit()*

**NAME** *m68360DevInit()* – initialize the SCC

**SYNOPSIS**

```
void m68360DevInit
(
 M68360_CHAN * pChan
)
```

**DESCRIPTION** This routine is called to initialize the chip to a quiescent state.

**SEE ALSO** *m68360Sio*

---

## *m68360Int()*

**NAME** *m68360Int()* – handle an SCC interrupt

**SYNOPSIS**

```
void m68360Int
(
 M68360_CHAN * pChan
)
```

**DESCRIPTION** This routine gets called to handle SCC interrupts.

**SEE ALSO** **m68360Sio**

---

## ***m68562HrdInit()***

**NAME** ***m68562HrdInit()*** – initialize the DUSCC

**SYNOPSIS**

```
void m68562HrdInit
(
 M68562_QUSART * pQusart
)
```

**DESCRIPTION** The BSP must have already initialized all the device addresses, etc in **M68562\_DUSART** structure. This routine resets the chip in a quiescent state.

**SEE ALSO** **m68562Sio**

---

## ***m68562RxInt()***

**NAME** ***m68562RxInt()*** – handle a receiver interrupt

**SYNOPSIS**

```
void m68562RxInt
(
 M68562_CHAN * pChan
)
```

**RETURNS** N/A

**SEE ALSO** **m68562Sio**

---

## ***m68562RxTxErrInt()***

**NAME** *m68562RxTxErrInt()* – handle a receiver/transmitter error interrupt

**SYNOPSIS**

```
void m68562RxTxErrInt
(
 M68562_CHAN * pChan
)
```

**DESCRIPTION** Only the receive overrun condition is handled.

**RETURNS** N/A

**SEE ALSO** **m68562Sio**

---

## ***m68562TxInt()***

**NAME** *m68562TxInt()* – handle a transmitter interrupt

**SYNOPSIS**

```
void m68562TxInt
(
 M68562_CHAN * pChan
)
```

**DESCRIPTION** If there is another character to be transmitted, it sends it. If not, or if a device has never been created for this channel, disable the interrupt.

**RETURNS** N/A

**SEE ALSO** **m68562Sio**

---

## ***m68681Acr()***

- NAME** *m68681Acr()* – return the contents of the DUART auxiliary control register
- SYNOPSIS**
- ```
UCHAR m68681Acr
(
    M68681_DUART * pDuart
)
```
- DESCRIPTION** This routine returns the contents of the auxilliary control register (ACR). The ACR is not directly readable; a copy of the last value written is kept in the DUART data structure.
- RETURNS** The contents of the auxilliary control register.
- SEE ALSO** **m68681Sio**

m68681AcrSetClr()

- NAME** *m68681AcrSetClr()* – set and clear bits in the DUART auxiliary control register
- SYNOPSIS**
- ```
void m68681AcrSetClr
(
 M68681_DUART * pDuart,
 UCHAR setBits, /* which bits to set in the ACR */
 UCHAR clearBits /* which bits to clear in the ACR */
)
```
- DESCRIPTION** This routine sets and clears bits in the DUART auxiliary control register (ACR). It sets and clears bits in a local copy of the ACR, then writes that local copy to the DUART. This means that all changes to the ACR must be performed by this routine. Any direct changes to the ACR are lost the next time this routine is called.
- Set has priority over clear. Thus you can use this routine to update multiple bit fields by specifying the field mask as the clear bits.
- RETURNS** N/A
- SEE ALSO** **m68681Sio**

---

|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>m68681DevInit()</i> – initialize a M68681_DUART                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <pre>void m68681DevInit (     M68681_DUART * pDuart )</pre>                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | The BSP must already have initialized all the device addresses and register pointers in the M68681_DUART structure as described in <b>m68681Sio</b> . This routine initializes some transmitter and receiver status values to be used in the interrupt mask register and then resets the chip to a quiescent state. |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                                                                 |
| <b>SEE ALSO</b>    | <b>m68681Sio</b>                                                                                                                                                                                                                                                                                                    |

## ***m68681Imr()***

**NAME** *m68681Imr()* – return the current contents of the DUART interrupt-mask register

**SYNOPSIS**

```
UCHAR m68681Imr
(
 M68681_DUART * pDuart
)
```

**DESCRIPTION** This routine returns the contents of the interrupt-mask register (IMR). The IMR is not directly readable; a copy of the last value written is kept in the DUART data structure.

**RETURNS** The contents of the interrupt-mask register.

**SEE ALSO** **m68681Sio**

---

## ***m68681ImrSetClr()***

**NAME** *m68681ImrSetClr()* – set and clear bits in the DUART interrupt-mask register

**SYNOPSIS**

```
void m68681ImrSetClr
(
 M68681_DUART * pDuart,
 UCHAR setBits, /* which bits to set in the IMR */
 UCHAR clearBits /* which bits to clear in the IMR */
)
```

**DESCRIPTION** This routine sets and clears bits in the DUART interrupt-mask register (IMR). It sets and clears bits in a local copy of the IMR, then writes that local copy to the DUART. This means that all changes to the IMR must be performed by this routine. Any direct changes to the IMR are lost the next time this routine is called.

Set has priority over clear. Thus you can use this routine to update multiple bit fields by specifying the field mask as the clear bits.

**RETURNS** N/A

**SEE ALSO** **m68681Sio**

| <b>DESCRIPTION</b> | <p>This routine returns the current state of the output port register (OPR) from the saved copy in the DUART data structure. The actual OPR contents are not directly readable.</p> |
| <b>RETURNS</b>     | The current state of the output port register.                                                                                                                                      |
| <b>SEE ALSO</b>    | <i>m68681Sio</i>                                                                                                                                                                    |

## *m68681OprSetClr()*

**NAME** *m68681OprSetClr()* – set and clear bits in the DUART output port register

**SYNOPSIS**

```
void m68681OprSetClr
(
 M68681_DUART * pDuart,
 UCHAR setBits, /* which bits to set in the OPR */
 UCHAR clearBits /* which bits to clear in the OPR */
)
```

**DESCRIPTION** This routine sets and clears bits in the DUART output port register (OPR). It sets and clears bits in a local copy of the OPR, then writes that local copy to the DUART. This means that all changes to the OPR must be performed by this routine. Any direct changes to the OPR are lost the next time this routine is called.

Set has priority over clear. Thus you can use this routine to update multiple bit fields by specifying the field mask as the clear bits.

**RETURNS** N/A

**SEE ALSO** *m68681Sio*

---

## *m68901DevInit()*

**NAME** *m68901DevInit()* – initialize a M68901\_CHAN structure

**SYNOPSIS**

```
void m68901DevInit
(
 M68901_CHAN * pChan
)
```

**DESCRIPTION** This routine initializes the driver function pointers and then resets the chip to a quiescent state. The BSP must have already initialized all the device addresses and the **baudFreq** fields in the M68901\_CHAN structure before passing it to this routine.

**RETURNS** N/A

**SEE ALSO** *m68901Sio*

## *malloc()*

|                    |                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>malloc()</i> – allocate a block of memory from the system memory partition (ANSI)                                                                             |
| <b>SYNOPSIS</b>    | <pre>void *malloc (     size_t nBytes /* number of bytes to allocate */ )</pre>                                                                                  |
| <b>DESCRIPTION</b> | This routine allocates a block of memory from the free list. The size of the block will be equal to or greater than <i>nBytes</i> .                              |
| <b>RETURNS</b>     | A pointer to the allocated block of memory, or a null pointer if there is an error.                                                                              |

## *masterIoInit()*

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>masterIoInit()</i> – create the IPC mechanism at the SNMP master agent                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <pre>STATUS masterIoInit ( void )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | <p>This routine, called from <i>snmpIoInit()</i>, creates the SNMP master agent side of the inter-process communication (IPC) mechanism used to carry messages between subagents and the master agent. In this implementation, <i>masterIoInit()</i> creates a single message queue. The identity of this message queue is hard coded into every subagent. The subagent puts a message on this queue when it needs to send a message to the master agent.</p> <p>The message queue created by <i>masterIoInit()</i> is monitored by <b>tMonQue</b>. The <b>tMonQue</b> task is one of the two tasks used to implement the SNMP master agent. The purpose of <b>tMonQue</b> is to note which messages in its queue are registration requests and which are responses to queries. If the message is a subagent registration request, <b>tMonQue</b> handles the request and sends a message back to the subagent telling it whether the registration was successful or not.</p> <p>If the message is a response to a query, <b>tMonQue</b> transfers the message to the message queue monitored by <b>tSnmpd</b>. The <b>tSnmpd</b> task then encodes the response in an SNMP packet and transmits the packet over a socket to the SNMP manager.</p> |

Although the shipped version of this function uses message queues as the IPC between the master agent and its subagents, the IPC mechanism is isolated to the relatively small number of functions defined in **masterIoLib**. Thus, if necessary, you should have little trouble porting the code to use an IPC more suitable to your transport needs.

For example, you could use sockets instead of message queues. However, if you decide to change the IPC mechanism, you must do so both in the master agent and in its subagents. This means that you must also modify the functions defined in **saIoLib**, the library that defines the agent side of the IPC mechanism.

**RETURNS** OK or ERROR.

**SEE ALSO** **masterIoLib**

---

## *masterIoWrite()*

**NAME** *masterIoWrite()* – send the encoded buffer to the subagent

**SYNOPSIS**

```
STATUS masterIoWrite
(
 EBUFFER_T * pBuf, /* reply message to be sent */
 PTR_T saId, /* subagent address */
 INT_32_T flg /* type of message */
)
```

**DESCRIPTION** This routine transmits the byte array at *pBuf* to the subagent at *saId*. This routine is called from a wide variety of functions in the master agent. For example, *masterIpcSend()* calls this routine when it needs to query the subagent about one of the MIB variables it manages. Likewise, the *masterIpcAyt()* function calls this routine when needs to check the IPC link status. Similarly, *snmpQueMonitor()* calls this routine to tell the agent the results of a registration or deregistration request.

The master agent uses the value *flg* to specify the general nature of the message it is writing to the subagent, which partially determines how the subagent responds. For example, when the master agent is responding to the subagent after successfully handling its registration request, the master agent uses a *flg* value of **REG\_COMPLETE**. When the master agent does an "are you there" check, it specifies a *flg* value of **IPC\_AYT**. **REG\_COMPLETE** and **IPC\_AYT** are the only currently valid *flg* values.

**RETURNS** OK or ERROR.

**SEE ALSO** **masterIoLib**

## *masterIpcAyt()*

- NAME** *masterIpcAyt()* – check the status of the IPC link
- SYNOPSIS**
- ```
INT_32_T masterIpcAyt
(
    PTR_T ipchandle /* pointer to IPC handle */
)
```
- DESCRIPTION** This is an "are you there" routine. The SNMP master agent calls this routine whenever it needs to do a status check on the IPC link to the address *ipchandle*. This routine puts a null-buffer message of type `IPC_AYT` on the subagent's message queue. If the subagent replies with a message of the same type, the link is considered active.
- RETURNS** 0, if the link is inactive; 1, if the link is inactive
- SEE ALSO** *masterIoLib*
-

masterIpcComp()

- NAME** *masterIpcComp()* – transmit a completion of transmission message
- SYNOPSIS**
- ```
void masterIpcComp
(
 OCTET_T opcode, /* this specifies what needs to be done */
 EBUFFER_T * ebuf, /* reply message to be sent */
 VBL_T * vblist, /* list of varbinds that the message contained */
 PTR_T ipchandle /* subagent address */
)
```
- DESCRIPTION** If the SNMP master agent uses *snmpMasterHandlerAsync()* to process a subagent's unsolicited control message (such as a registration request), it uses *masterIpcComp()* to complete processing for the message. In the current implementation, this means telling the subagent the completion status of a registration or deregistration request. However, you can rewrite this function to implement a broader range of responses (such as forwarding traps to the SNMP manager).
- When the master agent calls this routine, it uses *opcode* to indicate the processing status of the message. If the status indicates an error, *masterIpcComp()* drops the packet. If the status indicates success, the master agent uses the *ebuf* parameter to pass in a message for the subagent at *ipchandle*. Internally, *masterIpcComp()* calls *masterIoWrite()* to forward

the message to the specified subagent. If this message is the response to a successful registration request, it contains the group ID for the MIB variables just added to the master agent's MIB tree. The subagent needs this group ID for any deregistration request it might send later. It also uses this ID to register instances of the object just registered.

If the *opcode* is a value of 1 or greater (up to and including 127), the master agent uses the *vblist* parameter to pass in a varbind list that it extracted from the control message. In the current implementation, the *masterIpcComp()* routine does nothing with the message and returns. However, you could modify *masterIpcComp()* to process the message according to the value specified by *opcode*. For example, if *opcode* indicates a trap, you could forward the information at *vblist* to the SNMP manager.

Currently, **subagent.h** defines symbolic constants for opcodes 1 through 12 (with opcode 11, **SA\_TRAP\_REQUEST**, reserved for trap requests). You are free to use the remaining opcodes for message types specific to your implementation.

**RETURNS** N/A

**SEE ALSO** **masterIoLib**

---

## *masterIpcFree()*

**NAME** *masterIpcFree()* – free the IPC resources allocated by the SNMP master agent

**SYNOPSIS**

```
void masterIpcFree
(
 PTR_T ipchandle /* pointer to IPC handle */
)
```

**DESCRIPTION** The SNMP master agent calls this routine to free a pointer to an IPC handle. This is part of the deregistration process for an SNMP agent.

**RETURNS** N/A

**SEE ALSO** **masterIoLib**

---

## *masterIpcRcv()*

**NAME** *masterIpcRcv()* – wait for a reply from the subagent

**SYNOPSIS**

```
INT_32_T masterIpcRcv
(
 EBUFFER_T * pBuf, /* buffer to be filled */
 PTR_T ipchandle /* pointer to the IPC handle */
)
```

**DESCRIPTION** This routine waits for a response after query has been sent to the subagent. In the shipped implementation of the WindNet SNMP master agent, this function waits on a message queue that is local to the master agent. This message queue is used to facilitate communication between **tSnmpd**, the task that manages communication with the SNMP manager, and **tMonQue**, the task that manages communication between the SNMP master agent and its subagents.

In the shipped master agent code, subagents communicate with the master agent by putting messages on the message queue monitored by **tMonQue**. If the message is a control message, it is processed by *snmpMasterHandlerWR()*. If the message is a query response, it is transferred to the local message queue on which *masterIpcRcv()* is waiting. All of this is handled synchronously. Thus, while the master agent is waiting for a response from the subagent, it is blocked. Normally, the amount of time spent blocked is quite short and is not a problem.

However, it is an imperfect world, so it is possible that a response for a query never makes it back to the subagent. To handle this possibility, the shipped version of the WindNet SNMP master agent puts a timeout on its wait for a query response. If you should rewrite the SNMP master agent for any reason, make sure that you preserve this timeout.

**RETURNS** 0, if the packet was received successfully; 1, if an error or a timeout has caused the objects to be marked inactive and subsequently removed; 2, if the master agent will allow the current packet to be processed without freeing objects.

**SEE ALSO** **masterIoLib**

---

## *masterIpcSend()*

**NAME** *masterIpcSend()* – send a message to a subagent

**SYNOPSIS**

```
INT_32_T masterIpcSend
(
 EBUFFER_T * pBuf, /* message to be sent */
 PTR_T ipchandle /* address of subagent */
)
```

**DESCRIPTION** The SNMP master agent calls when it needs to send a query in *buf* to the subagent at the *ipchandle* address. If this routine is used with *snmpMasterHandlerAsync()*, you must rewrite the function according to the prototype of `IPSEND_AS_T` (see `subagent.h`). The additional parameter *reqid* in this prototype is the request ID of the message being sent. Use *reqid* to call *snmpMasterCleanup()* if the IPC layer times out.

Internally, this function calls *masterIoWrite()* to put a message on the subagent's message queue. If you have rewritten *masterIoWrite()* to use different IPC mechanism, such as sockets, you should take care that your rewrite of *masterIoWrite()* is compatible with its use in *masterIpcSend()*.

**RETURNS** 0, if the packet has been sent successfully; 1, if an error has been detected that caused the objects to be marked inactive and possibly removed; 2, if the processing of the current packet is allowed to continue without freeing up objects.

**SEE ALSO** *masterIoLib*

---

## *masterQueCleanup()*

**NAME** *masterQueCleanup()* – free resources allocated for SNMP master agent

**SYNOPSIS**

```
void masterQueCleanup (void)
```

**DESCRIPTION** This routine is called from the cleanup routine in `snmpIoLib` if the agent fails to allocate resources. This routine deletes the message queue and all other resources that have been allocated for the master agent.

**RETURNS** N/A

**SEE ALSO** *masterIoLib*

***mathHardInit()***

---

***mathHardInit()***

**NAME** *mathHardInit()* – initialize hardware floating-point math support

**SYNOPSIS** `void mathHardInit ()`

**DESCRIPTION** This routine places the addresses of the hardware high-level math functions (trigonometric functions, etc.) in a set of global variables. This allows the standard math functions (e.g., *sin()*, *pow()*) to have a single entry point but to be dispatched to the hardware or software support routines, as specified.

This routine is called from `usrConfig.c` if `INCLUDE_HW_FP` is defined. This definition causes the linker to include the floating-point hardware support library.

Certain routines in the floating-point software emulation library do not have equivalent hardware support routines. (These are primarily routines that handle single-precision floating-point numbers.) If no emulation routine address has already been put in the global variable for this function, the address of a dummy routine that logs an error message is placed in the variable; if an emulation routine address is present (the emulation initialization, via *mathSoftInit()*, must be done prior to hardware floating-point initialization), the emulation routine address is left alone. In this way, hardware routines will be used for all available functions, while emulation will be used for the missing functions.

**RETURNS** N/A

**SEE ALSO** `mathHardLib`, *mathSoftInit()*

---

***mathSoftInit()***

**NAME** *mathSoftInit()* – initialize software floating-point math support

**SYNOPSIS** `void mathSoftInit ()`

**DESCRIPTION** This routine places the addresses of the emulated high-level math functions (trigonometric functions, etc.) in a set of global variables. This allows the standard math functions (e.g., *sin()*, *pow()*) to have a single entry point but be dispatched to the hardware or software support routines, as specified.

This routine is called from `usrConfig.c` if `INCLUDE_SW_FP` is defined. This definition causes the linker to include the floating-point emulation library.

If the system is to use some combination of emulated as well as hardware coprocessor floating points, then this routine should be called before calling *mathHardInit()*.

**RETURNS** N/A

**SEE ALSO** *mathSoftLib*, *mathHardInit()*

## ***mb86940DevInit()***

**NAME** *mb86940DevInit()* – install the driver function table

**SYNOPSIS**

```
void mb86940DevInit
(
 MB86940_CHAN * pChan
)
```

**DESCRIPTION** This routine installs the driver function table. It also prevents the serial channel from functioning by disabling the interrupt.

**RETURNS** N/A

**SEE ALSO** *mb86940Sio*

## ***mb86960EndLoad()***

**NAME** *mb86960EndLoad()* – initialize the driver and device

**SYNOPSIS**

```
END_OBJ * mb86960EndLoad
(
 char * pInitString /* String to be parsed by the driver. */
)
```

**DESCRIPTION** This routine initializes the driver and puts the device to an operational state. All of the device specific parameters are passed in via the *initString*, which expects a string of the following format:

*unit:base\_addr:int\_vector:int\_level*

This routine can be called in two modes. If it is called with an empty but allocated string, it places the name of this device (that is, "fn") into the *initString* and returns 0.

If the string is allocated and not empty, the routine attempts to load the driver using the values specified in the string.

**RETURNS** An END object pointer, or NULL on error, or 0 and the name of the device if the *initString* was NULL.

**SEE ALSO** ***mb86960End***

---

## ***mb86960InitParse( )***

**NAME** ***mb86960InitParse( )*** – parse the initialization string

**SYNOPSIS**

```
STATUS mb86960InitParse
(
 MB86960_END_CTRL * pDrvCtrl, /* device pointer */
 char * pInitString /* information string */
)
```

**DESCRIPTION** Parse the input string. Fill in values in the driver control structure.

The initialization string format is:

*unit:baseAddr:ivec*

*unit*

Device unit number, a small integer. MUST always be 0.

*devBaseAddr*

Base address of the device register set

*ivec*

Interrupt vector number (used with `sysIntConnect`)

**RETURNS** OK or ERROR for invalid arguments.

**SEE ALSO** ***mb86960End***

---

## *mb86960MemInit()*

**NAME** *mb86960MemInit()* – initialize memory for the chip

**SYNOPSIS**

```
STATUS mb86960MemInit
(
 MB86960_END_CTRL * pDrvCtrl /* device to be initialized */
)
```

**DESCRIPTION** This routine is highly specific to the device.

**RETURNS** OK or ERROR.

**SEE ALSO** *mb86960End*

---

## *mb87030CtrlCreate()*

**NAME** *mb87030CtrlCreate()* – create a control structure for an MB87030 SPC

**SYNOPSIS**

```
MB_87030_SCSI_CTRL *mb87030CtrlCreate
(
 UINT8 * spcBaseAdrs, /* base address of SPC */
 int regOffset, /* addr offset between consecutive regs. */
 UINT clkPeriod, /* period of controller clock (nsec) */
 int spcDataParity, /* type of input to SPC DP (data parity) */
 FUNCPTR spcDMABytesIn, /* SCSI DMA input function */
 FUNCPTR spcDMABytesOut /* SCSI DMA output function */
)
```

**DESCRIPTION** This routine creates a data structure that must exist before the SPC chip can be used. This routine should be called once and only once for a specified SPC. It should be the first routine called, since it allocates memory for a structure needed by all other routines in the library.

After calling this routine, at least one call to *mb87030CtrlInit()* should be made before any SCSI transaction is initiated using the SPC chip.

A detailed description of the input parameters follows:

*spcBaseAdrs*  
the address at which the CPU would access the lowest register of the SPC.

*regOffset*

the address offset (bytes) to access consecutive registers. (This must be a power of 2, for example, 1, 2, 4, etc.)

*clkPeriod*

the period in nanoseconds of the signal to the SPC clock input (only used for select command timeouts).

*spcDataParity*

the parity bit must be defined by one of the following constants, according to whether the input to SPC DP is GND, +5V, or a valid parity signal, respectively:

```
SPC_DATA_PARITY_LOW
SPC_DATA_PARITY_HIGH
SPC_DATA_PARITY_VALID
```

*spcDmaBytesIn* and *spcDmaBytesOut*

pointers to board-specific routines to handle DMA input and output. If these are NULL (0), SPC program transfer mode is used. DMA is possible only during SCSI data in/out phases. The interface to these DMA routines must be of the form:

```
STATUS xxDmaBytes{In, Out}
(
 SCSI_PHYS_DEV *pScsiPhysDev, /* ptr to phys dev info */
 UINT8 *pBuffer, /* ptr to the data buffer */
 int bufLength /* number of bytes to xfer */
)
```

**RETURNS** A pointer to the SPC control structure, or NULL if memory is insufficient or parameters are invalid.

**SEE ALSO** [mb87030Lib](#)

---

## ***mb87030CtrlInit()***

**NAME** *mb87030CtrlInit()* – initialize a control structure for an MB87030 SPC

**SYNOPSIS**

```
STATUS mb87030CtrlInit
(
 MB_87030_SCSI_CTRL * pSpc, /* ptr to SPC struct */
 int scsiCtrlBusId, /* SCSI bus ID of this SPC */
 UINT defaultSelTimeout, /* default dev sel timeout */
 int scsiPriority /* priority of task doing SCSI */
)
```

**DESCRIPTION** This routine initializes an SPC control structure created by *mb87030CtrlCreate()*. It must be called before the SPC is used. This routine can be called more than once; however, it should be called only while there is no activity on the SCSI interface.

Before returning, this routine pulses RST (reset) on the SCSI bus, thus resetting all attached devices.

The input parameters are as follows:

*pSpc*  
a pointer to the **MB\_87030\_SCSI\_CTRL** structure created with *mb87030CtrlCreate()*.

*scsiCtrlBusId*  
the SCSI bus ID of the SIOP, in the range 0 – 7. The ID is somewhat arbitrary; the value 7, or highest priority, is conventional.

*defaultSelTimeOut*  
the timeout, in microseconds, for selecting a SCSI device attached to this controller. The recommended value 0 specifies **SCSI\_DEF\_SELECT\_TIMEOUT** (250 milliseconds). The maximum timeout possible is approximately 3 seconds. Values exceeding this revert to the maximum.

*scsiPriority*  
the priority to which a task is set when performing a SCSI transaction. Valid priorities range from 0 to 255. Alternatively, the value -1 specifies that the priority should not be altered during SCSI transactions.

**RETURNS** OK, or ERROR if parameters are out of range.

**SEE ALSO** **mb87030Lib**

---

## ***mb87030Show()***

**NAME** *mb87030Show()* – display the values of all readable MB87030 SPC registers

**SYNOPSIS**

```
STATUS mb87030Show
(
 SCSI_CTRL * pScsiCtrl /* ptr to SCSI controller info */
)
```

**DESCRIPTION** This routine displays the state of the SPC registers in a user-friendly manner. It is useful primarily for debugging.

**EXAMPLE**

```
-> mb87030Show
SCSI Bus ID: 7
```

***mbcAddrFilterSet()***

```

SCTL (0x01): intsEnbl
SCMD (0x00): busRlease
TMOD (0x00): asyncMode
INTS (0x00):
PSNS (0x00): req0 ack0 atn0 sel0 bsy0 msg0 c_d0 i_o0
SSTS (0x05): noConIdle xferCnt=0 dregEmpty
SERR (0x00): noParErr
PCTL (0x00): bfIntDsbl phDataOut
MBC (0x00): 0
XFER COUNT : 0x000000 = 0

```

**RETURNS** OK, or ERROR if *pScsiCtrl* and *pSysScsiCtrl* are both NULL.

**SEE ALSO** **mb87030Lib**

***mbcAddrFilterSet()***

**NAME** *mbcAddrFilterSet()* – set the address filter for multicast addresses

**SYNOPSIS**

```

void mbcAddrFilterSet
(
 MBC_DEVICE * pDrvCtrl /* device to be updated */
)

```

**DESCRIPTION** This routine goes through all of the multicast addresses on the list of addresses (added with the *endAddrAdd()* routine) and sets the device's filter correctly.

**RETURNS** N/A.

**SEE ALSO** **mbcEnd**

***mbcattach()***

**NAME** *mbcattach()* – publish the **mbc** network interface and initialize the driver

**SYNOPSIS**

```

STATUS mbcattach
(
 int unit, /* unit number */
 void * pEmBase, /* ethernet module base address */

```

```

int inum, /* interrupt vector number */
int txBdNum, /* number of transmit buffer descriptors */
int rxBdNum, /* number of receive buffer descriptors */
int dmaParms, /* DMA parameters */
UINT8 * bufBase /* address of memory pool; NONE = malloc it */
)

```

**DESCRIPTION** The routine publishes the **mbc** interface by adding an **mbc** Interface Data Record (IDR) to the global network interface list.

The Ethernet controller uses buffer descriptors from an on-chip dual-ported RAM region, while the buffers are allocated in RAM external to the controller. The buffer memory pool can be allocated in a non-cacheable RAM region and passed as parameter *bufBase*.

Otherwise *bufBase* is NULL and the buffer memory pool is allocated by the routine using *cacheDmaMalloc()*. The driver uses this buffer pool to allocate the specified number of 1518-byte buffers for transmit, receive, and loaner pools.

The parameters *txBdNum* and *rxBdNum* specify the number of buffers to allocate for transmit and receive. If either of these parameters is NULL, the default value of 2 is used. The number of loaner buffers allocated is the lesser of *rxBdNum* and 16.

The on-chip dual ported RAM can only be partitioned so that the maximum receive and maximum transmit BDs are:

- Transmit BDs: 8, Receive BDs: 120
- Transmit BDs: 16, Receive BDs: 112
- Transmit BDs: 32, Receive BDs: 96
- Transmit BDs: 64, Receive BDs: 64

**RETURNS** ERROR, if *unit* is out of range or non-cacheable memory cannot be allocated; otherwise TRUE.

**SEE ALSO** *if\_mbc*, *ifLib*, *Motorola MC68EN302 User's Manual*

---

## ***mbcEndLoad()***

**NAME** *mbcEndLoad()* – initialize the driver and device

**SYNOPSIS**

```

END_OBJ* mbcEndLoad
(
 char * initString /* String to be parsed by the driver. */
)

```

***mbcIntr()***

|                    |                                                                                                                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | This routine initializes the driver and the device to the operational state. All of the device specific parameters are passed in the <code>initString</code> .<br><br>The string contains the target specific parameters like this:<br><code>"unit:memAddr:ivec:txBdNum:rxBdNum:dmaParms:bufBase:offset"</code> |
| <b>RETURNS</b>     | An END object pointer or NULL on error.                                                                                                                                                                                                                                                                         |
| <b>SEE ALSO</b>    | <code>mbcEnd</code>                                                                                                                                                                                                                                                                                             |

---

|--------------------|-------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <code>mbcMemInit()</code> – initialize memory for the chip                                |
| <b>SYNOPSIS</b>    | <pre>STATUS mbcMemInit (     MBC_DEVICE * pDrvCtrl /* device to be initialized */ )</pre> |
| <b>DESCRIPTION</b> | Allocates and initializes the memory pools for the mbc device.                            |

**RETURNS** OK or ERROR.

**SEE ALSO** **mbcEnd**

---

## *mbcParse()*

**NAME** *mbcParse()* – parse the init string

**SYNOPSIS**

```
STATUS mbcParse
(
 MBC_DEVICE * pDrvCtrl, /* device pointer */
 char * initString /* information string */
)
```

**DESCRIPTION** Parse the input string. Fill in values in the driver control structure.

The initialization string format is:

*unit:memAddr:ivec:txBdNum:rxBdNum:dmaParms:bufBase:offset*

*unit*

Device unit number, a small integer.

*memAddr*

ethernet module base address.

*ivec*

Interrupt vector number (used with sysIntConnect)

*txBdNum*

transmit buffer descriptor

*rxBdNum*

receive buffer descriptor

*dmaParms*

dma parameters

*bufBase*

address of memory pool

*offset*

packet data offset

**RETURNS** OK or ERROR for invalid arguments.

**SEE ALSO** **mbcEnd**

---

## ***mbcStartOutput()***

**NAME** *mbcStartOutput()* – output packet to network interface device

**SYNOPSIS**

```
#ifdef BSD43_DRIVER LOCAL void mbcStartOutput
(
 int unit /* unit number */
)
```

**DESCRIPTION** *mbcStartOutput()* takes a packet from the network interface output queue, copies the mbuf chain into an interface buffer, and sends the packet over the interface. etherOutputHookRtns are supported.

Collision stats are collected in this routine from previously sent BDs. These BDs will not be examined until after the transmitter has cycled the ring, coming upon the BD after it has been sent. Thus, collision stat collection will be delayed a full cycle through the Tx ring.

This routine is called under several possible scenarios. Each one will be described below.

The first, and most common, is when a user task requests the transmission of data. Under BSD 4.3, this results in a call to *mbcOutput()*, which in turn calls *ether\_output()*. The routine, *ether\_output()*, will make a call to *mbcStartOutput()* if our interface output queue is not full, otherwise, the outgoing data is discarded. BSD 4.4 uses a slightly different model, in which the generic *ether\_output()* routine is called directly, followed by a call to this routine.

The second scenario is when this routine, while executing runs out of free Tx BDs, turns on transmit interrupts and exits. When the next BD is transmitted, an interrupt occurs and the ISR does a *netJobAdd* of the routine which executes in the context of *netTask()* and continues sending packets from the interface output queue.

The third scenario is when the device is reset, typically when the promiscuous mode is altered; which results in a call to *mbcInit()*. This resets the device, does a *netJobAdd()* of this routine to enable transmitting queued packets.

**RETURNS** N/A

---

## ***mblen()***

**NAME** *mblen()* – calculate the length of a multibyte character (Unimplemented) (ANSI)

**SYNOPSIS**

```
int mblen
(
 const char * s,
 size_t n
)
```

**DESCRIPTION** This multibyte character function is unimplemented in VxWorks.

**INCLUDE FILES** **stdlib.h**

**RETURNS** OK, or ERROR if the parameters are invalid.

**SEE ALSO** **ansiStdlib**

---

## ***mbstowcs()***

**NAME** *mbstowcs()* – convert a series of multibyte char's to wide char's (Unimplemented) (ANSI)

**SYNOPSIS**

```
size_t mbstowcs
(
 wchar_t * pwcs,
 const char * s,
 size_t n
)
```

**DESCRIPTION** This multibyte character function is unimplemented in VxWorks.

**INCLUDE FILES** **stdlib.h**

**RETURNS** OK, or ERROR if the parameters are invalid.

**SEE ALSO** **ansiStdlib**

## *memalign()*

|                    |                                                                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>memalign()</i> – allocate aligned memory                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <pre>void *memalign (     unsigned alignment, /* boundary to align to (power of 2) */     unsigned size      /* number of bytes to allocate */ )</pre>                                                                                                                   |
| <b>DESCRIPTION</b> | This routine allocates a buffer of size <i>size</i> from the system memory partition. Additionally, it insures that the allocated buffer begins on a memory address evenly divisible by the specified alignment parameter. The alignment parameter must be a power of 2. |
| <b>RETURNS</b>     | A pointer to the newly allocated block, or NULL if the buffer could not be allocated.                                                                                                                                                                                    |
| <b>SEE ALSO</b>    | <i>memLib</i>                                                                                                                                                                                                                                                            |

## *memchr()*

|                      |                                                                                                                                                                                                      |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>memchr()</i> – search a block of memory for a character (ANSI)                                                                                                                                    |
| <b>SYNOPSIS</b>      | <pre>void * memchr (     const void * m, /* block of memory */     int         c, /* character to search for */     size_t      n  /* size of memory to search */ )</pre>                            |
| <b>DESCRIPTION</b>   | This routine searches for the first element of an array of <b>unsigned char</b> , beginning at the address <i>m</i> with size <i>n</i> , that equals <i>c</i> converted to an <b>unsigned char</b> . |
| <b>INCLUDE FILES</b> | <b>string.h</b>                                                                                                                                                                                      |
| <b>RETURNS</b>       | If successful, it returns the address of the matching element; otherwise, a null pointer.                                                                                                            |
| <b>SEE ALSO</b>      | <b>ansiString</b>                                                                                                                                                                                    |

## *memcmp()*

|                      |                                                                                                                                                                                                                           |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>memcmp()</i> – compare two blocks of memory (ANSI)                                                                                                                                                                     |
| <b>SYNOPSIS</b>      | <pre>int memcmp (     const void * s1, /* array 1 */     const void * s2, /* array 2 */     size_t      n  /* size of memory to compare */ )</pre>                                                                        |
| <b>DESCRIPTION</b>   | This routine compares successive elements from two arrays of <b>unsigned char</b> , beginning at the addresses <i>s1</i> and <i>s2</i> (both of size <i>n</i> ), until it finds elements that are not equal.              |
| <b>INCLUDE FILES</b> | <b>string.h</b>                                                                                                                                                                                                           |
| <b>RETURNS</b>       | If all elements are equal, zero. If elements differ and the differing element from <i>s1</i> is greater than the element from <i>s2</i> , the routine returns a positive number; otherwise, it returns a negative number. |
| <b>SEE ALSO</b>      | <b>ansiString</b>                                                                                                                                                                                                         |

---

## *memcpy()*

**NAME** *memcpy()* – copy memory from one location to another (ANSI)

**SYNOPSIS**

```
void * memcpy
(
 void * destination, /* destination of copy */
 const void * source, /* source of copy */
 size_t size /* size of memory to copy */
)
```

**DESCRIPTION** This routine copies *size* characters from the object pointed to by *source* into the object pointed to by *destination*. If copying takes place between objects that overlap, the behavior is undefined.

**INCLUDE FILES** *string.h*

**RETURNS** A pointer to *destination*.

**SEE ALSO** *ansiString*

---

## *memDevCreate()*

**NAME** *memDevCreate()* – create a memory device

**SYNOPSIS**

```
STATUS memDevCreate
(
 char * name, /* device name */
 char * base, /* where to start in memory */
 int length /* number of bytes */
)
```

**DESCRIPTION** This routine creates a memory device containing a single file. Memory for the device is simply an absolute memory location beginning at *base*. The *length* parameter indicates the size of memory.

For example, to create the device *"/mem/cpu0/"*, a device for accessing the entire memory of the local processor, the proper call would be:

```
memDevCreate ("/mem/cpu0/", 0, sysMemTop())
```

The device is created with the specified name, start location, and size.

To open a file descriptor to the memory, use *open()*. Specify a pseudo-file name of the byte offset desired, or open the "raw" file at the beginning and specify a position to seek to. For example, the following call to *open()* allows memory to be read starting at decimal offset 1000.

```
-> fd = open ("/mem/cpu0/1000", O_RDONLY, 0)
```

Pseudo-file name offsets are scanned with "%d".

**CAVEAT** The FIOSEEK operation overrides the offset given via the pseudo-file name at open time.

**EXAMPLE** Consider a system configured with two CPUs in the backplane and a separate dual-ported memory board, each with 1 megabyte of memory. The first CPU is mapped at VMEbus address 0x00400000 (4 Meg.), the second at bus address 0x00800000 (8 Meg.), the dual-ported memory board at 0x00c00000 (12 Meg.). Three devices can be created on each CPU as follows. On processor 0:

```
-> memDevCreate ("/mem/local/", 0, sysMemTop())
...
-> memDevCreate ("/mem/cpu1/", 0x00800000, 0x00100000)
...
-> memDevCreate ("/mem/share/", 0x00c00000, 0x00100000)
```

On processor 1:

```
-> memDevCreate ("/mem/local/", 0, sysMemTop())
...
-> memDevCreate ("/mem/cpu0/", 0x00400000, 0x00100000)
...
-> memDevCreate ("/mem/share/", 0x00c00000, 0x00100000)
```

Processor 0 has a local disk. Data or an object module needs to be passed from processor 0 to processor 1. To accomplish this, processor 0 first calls:

```
-> copy </disk1/module.o >/mem/share/0
```

Processor 1 can then be given the load command:

```
-> ld </mem/share/0
```

**RETURNS** OK, or ERROR if memory is insufficient or the I/O system cannot add the device.

**ERRNO** S\_ioLib\_NO\_DRIVER

**SEE ALSO** memDrv

| <b>SYNOPSIS</b>    | <pre>STATUS memDevCreateDir (     char *          name,      /* device name */     MEM_DRV_DIRENTRY * files, /* array of dir. entries - not copied */     int             numFiles /* number of entries */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>This routine creates a memory device for a collection of files organised into directories. The given array of directory entry records describes a number of files, some of which may be directories, represented by their own directory entry arrays. The structure may be arbitrarily deep. This effectively allows a filesystem to be created and installed in VxWorks, for essentially read-only use. The filesystem structure can be created on the host using the memdrvbuild utility.</p> <p>Note that the array supplied is not copied; a reference to it is kept. This array should not be modified after being passed to memDevCreateDir.</p> |
| <b>RETURNS</b>     | OK, or ERROR if memory is insufficient or the I/O system cannot add the device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ERRNO</b>       | S_ioLib_NO_DRIVER                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## *memDevDelete()*

|                    |                                                                                                                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>memDevDelete()</i> – delete a memory device                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <pre>STATUS memDevDelete (     char * name /* device name */ )</pre>                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>This routine deletes a memory device containing a single file or a collection of files. The device is deleted with its own name.</p> <p>For example, to delete the device created by memDevCreate ("/mem/cpu0/", 0, <i>sysMemTop()</i>), the proper call would be:</p> |

```
memDevDelete ("/mem/cpu0/");
```

**RETURNS** OK, or ERROR if the device doesn't exist.

**SEE ALSO** **memDrv**

---

## ***memDrv()***

**NAME** *memDrv()* – install a memory driver

**SYNOPSIS** `STATUS memDrv (void)`

**DESCRIPTION** This routine initializes the memory driver. It must be called first, before any other routine in the driver.

**RETURNS** OK, or ERROR if the I/O system cannot install the driver.

**SEE ALSO** **memDrv**

---

## ***memFindMax()***

**NAME** *memFindMax()* – find the largest free block in the system memory partition

**SYNOPSIS** `int memFindMax (void)`

**DESCRIPTION** This routine searches for the largest block in the system memory partition free list and returns its size.

**RETURNS** The size, in bytes, of the largest available block.

**SEE ALSO** **memLib**, **memPartFindMax()**

---

## *memmove()*

|                      |                                                                                                                                                                                                                          |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>memmove()</i> – copy memory from one location to another (ANSI)                                                                                                                                                       |
| <b>SYNOPSIS</b>      | <pre>void * memmove (     void *      destination, /* destination of copy */     const void * source,    /* source of copy */     size_t     size        /* size of memory to copy */ )</pre>                            |
| <b>DESCRIPTION</b>   | This routine copies <i>size</i> characters from the memory location <i>source</i> to the location <i>destination</i> . It ensures that the memory is not corrupted even if <i>source</i> and <i>destination</i> overlap. |
| <b>INCLUDE FILES</b> | <b>string.h</b>                                                                                                                                                                                                          |
| <b>RETURNS</b>       | A pointer to <i>destination</i> .                                                                                                                                                                                        |
| <b>SEE ALSO</b>      | <b>ansiString</b>                                                                                                                                                                                                        |

## *memOptionsSet()*

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>memOptionsSet()</i> – set the debug options for the system memory partition                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <pre>void memOptionsSet (     unsigned options /* options for system partition */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>This routine sets the debug options for the system memory partition. Two kinds of errors are detected: attempts to allocate more memory than is available, and bad blocks found when memory is freed. In both cases, the following options can be selected for actions to be taken when the error is detected: (1) return the error status, (2) log an error message and return the error status, or (3) log an error message and suspend the calling task.</p> <p>These options are discussed in detail in the library manual entry for <b>memLib</b>.</p> |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SEE ALSO</b>    | <b>memLib</b> , <i>memPartOptionsSet()</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## ***memPartAddToPool()***

**NAME** *memPartAddToPool()* – add memory to a memory partition

**SYNOPSIS**

```
STATUS memPartAddToPool
(
 PART_ID partId, /* partition to initialize */
 char * pPool, /* pointer to memory block */
 unsigned poolSize /* block size in bytes */
)
```

**DESCRIPTION** This routine adds memory to a specified memory partition already created with *memPartCreate()*. The memory added need not be contiguous with memory previously assigned to the partition.

**RETURNS** OK or ERROR.

**ERRNO** S\_smObjLib\_NOT\_INITIALIZED, S\_memLib\_INVALID\_NBYTES

**SEE ALSO** *memPartLib*, *smMemLib*, *memPartCreate()*

---

## ***memPartAlignedAlloc()***

**NAME** *memPartAlignedAlloc()* – allocate aligned memory from a partition

**SYNOPSIS**

```
void *memPartAlignedAlloc
(
 PART_ID partId, /* memory partition to allocate from */
 unsigned nBytes, /* number of bytes to allocate */
 unsigned alignment /* boundary to align to */
)
```

**DESCRIPTION** This routine allocates a buffer of size *nBytes* from a specified partition. Additionally, it insures that the allocated buffer begins on a memory address evenly divisible by *alignment*. The *alignment* parameter must be a power of 2.

**RETURNS** A pointer to the newly allocated block, or NULL if the buffer could not be allocated.

**SEE ALSO** *memPartLib*

---

|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>memPartAlloc()</i> – allocate a block of memory from a partition                                                                                                                                             |
| <b>SYNOPSIS</b>    | <pre>void *memPartAlloc (     PART_ID partId, /* memory partition to allocate from */     unsigned nBytes /* number of bytes to allocate */ )</pre>                                                             |
| <b>DESCRIPTION</b> | This routine allocates a block of memory from a specified partition. The size of the block will be equal to or greater than <i>nBytes</i> . The partition must already be created with <i>memPartCreate()</i> . |
| <b>RETURNS</b>     | A pointer to a block, or NULL if the call fails.                                                                                                                                                                |
| <b>ERRNO</b>       | S_smObjLib_NOT_INITIALIZED                                                                                                                                                                                      |
| <b>SEE ALSO</b>    | <i>memPartLib</i> , <i>smMemLib</i> , <i>memPartCreate()</i>                                                                                                                                                    |

## *memPartCreate()*

|                    |                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>memPartCreate()</i> – create a memory partition                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <pre>PART_ID memPartCreate (     char * pPool, /* pointer to memory area */     unsigned poolSize /* size in bytes */ )</pre>                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | This routine creates a new memory partition containing a specified memory pool. It returns a partition ID, which can then be passed to other routines to manage the partition (i.e., to allocate and free memory blocks in the partition). Partitions can be created to manage any number of separate memory pools. |
| <b>NOTE</b>        | The descriptor for the new partition is allocated out of the system memory partition (i.e., with <i>malloc()</i> ).                                                                                                                                                                                                 |
| <b>RETURNS</b>     | The partition ID, or NULL if there is insufficient memory in the system memory partition for a new partition descriptor.                                                                                                                                                                                            |

## *memPartFindMax()*

**NAME** *memPartFindMax()* – find the size of the largest available free block

**SYNOPSIS**

```
int memPartFindMax
(
 PART_ID partId /* partition ID */
)
```

**DESCRIPTION** This routine searches for the largest block in the memory partition free list and returns its size.

**RETURNS** The size, in bytes, of the largest available block.

**ERRNO** *S\_smObjLib\_NOT\_INITIALIZED*

SEE ALSO *memLib*, *smMemLib*

---

## *memPartFree()*

**NAME** *memPartFree()* – free a block of memory in a partition

**SYNOPSIS**

```
STATUS memPartFree
(
 PART_ID partId, /* memory partition to add block to */
 char * pBlock /* pointer to block of memory to free */
)
```

**DESCRIPTION** This routine returns to a partition's free memory list a block of memory previously allocated with *memPartAlloc()*.

**RETURNS** OK, or ERROR if the block is invalid.

**ERRNO** *S\_smObjLib\_NOT\_INITIALIZED*

SEE ALSO *memPartLib*, *smMemLib*, *memPartAlloc()*

## *memPartOptionsSet()*

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>memPartOptionsSet()</i> – set the debug options for a memory partition                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <pre>STATUS memPartOptionsSet (     PART_ID partId, /* partition to set option for */     unsigned options /* memory management options */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>This routine sets the debug options for a specified memory partition. Two kinds of errors are detected: attempts to allocate more memory than is available, and bad blocks found when memory is freed. In both cases, the error status is returned. There are four error-handling options that can be individually selected:</p> <p><b>MEM_ALLOC_ERROR_LOG_FLAG</b><br/>Log a message when there is an error in allocating memory.</p> <p><b>MEM_ALLOC_ERROR_SUSPEND_FLAG</b><br/>Suspend the task when there is an error in allocating memory (unless the task was spawned with the VX_UNBREAKABLE option, in which case it cannot be suspended).</p> <p><b>MEM_BLOCK_ERROR_LOG_FLAG</b><br/>Log a message when there is an error in freeing memory.</p> |

***memPartRealloc()*****MEM\_BLOCK\_ERROR\_SUSPEND\_FLAG**

Suspend the task when there is an error in freeing memory (unless the task was spawned with the **VX\_UNBREAKABLE** option, in which case it cannot be suspended).

These options are discussed in detail in the library manual entry for **memLib**.

|                    |                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>memPartRealloc()</i> – reallocate a block of memory in a specified partition                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <pre>void *memPartRealloc (     PART_ID partId, /* partition ID */     char * pBlock, /* block to be reallocated */     unsigned nBytes /* new block size in bytes */ ) </pre>                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>This routine changes the size of a specified block of memory and returns a pointer to the new block. The contents that fit inside the new size (or old size if smaller) remain unchanged. The memory alignment of the new block is not guaranteed to be the same as the original block.</p> <p>If <i>pBlock</i> is NULL, this call is equivalent to <i>memPartAlloc()</i>.</p> |
| <b>RETURNS</b>     | A pointer to the new block of memory, or NULL if the call fails.                                                                                                                                                                                                                                                                                                                  |
| <b>ERRNO</b>       | S_smObjLib_NOT_INITIALIZED                                                                                                                                                                                                                                                                                                                                                        |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>memPartShow()</i> – show partition blocks and statistics                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <pre>STATUS memPartShow (     PART_ID partId, /* partition ID */     int     type    /* 0 = statistics, 1 = statistics &amp; list */ )</pre>                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>This routine displays statistics about the available and allocated memory in a specified memory partition. It shows the number of bytes, the number of blocks, and the average block size in both free and allocated memory, and also the maximum block size of free memory. It also shows the number of blocks currently allocated and the average allocated block size.</p> <p>In addition, if <i>type</i> is 1, the routine displays a list of all the blocks in the free list of the specified partition.</p> |
| <b>RETURNS</b>     | OK or ERROR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ERRNO</b>       | S_smObjLib_NOT_INITIALIZED                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## *memPartSmCreate()*

|                    |                                                                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>memPartSmCreate()</i> – create a shared memory partition (VxMP Opt.)                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <pre>PART_ID memPartSmCreate (     char *  pPool, /* global address of shared memory area */     unsigned poolSize /* size in bytes */ )</pre>                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>This routine creates a shared memory partition that can be used by tasks on all CPUs in the system. It returns a partition ID which can then be passed to generic <b>memPartLib</b> routines to manage the partition (i.e., to allocate and free memory blocks in the partition).</p> |

**memset()**

*pPool* is the global address of shared memory dedicated to the partition. The memory area pointed to by *pPool* must be in the same address space as the shared memory anchor and shared memory pool.

*poolSize* is the size in bytes of shared memory dedicated to the partition.

Before this routine can be called, the shared memory objects facility must be initialized (see **smMemLib**).

|                     |                                                                                                                                                                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NOTE</b>         | The descriptor for the new partition is allocated out of an internal dedicated shared memory partition. The maximum number of partitions that can be created is <b>SM_OBJ_MAX_MEM_PART</b> .<br><br>Memory pool size is rounded down to a 16-byte boundary. |
| <b>AVAILABILITY</b> | This routine is distributed as a component of the unbundled shared memory objects support option, VxMP.                                                                                                                                                     |
| <b>RETURNS</b>      | The partition ID, or NULL if there is insufficient memory in the dedicated partition for a new partition descriptor.                                                                                                                                        |
| <b>ERRNO</b>        | <b>S_memLib_NOT_ENOUGH_MEMORY</b><br><b>S_smObjLib_LOCK_TIMEOUT</b>                                                                                                                                                                                         |
| <b>SEE ALSO</b>     | <b>smMemLib</b> , <b>memLib</b>                                                                                                                                                                                                                             |

---

**memset()**

|                      |                                                                                                                                                                                |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>memset()</i> – set a block of memory (ANSI)                                                                                                                                 |
| <b>SYNOPSIS</b>      | <pre>void * memset (     void * m,    /* block of memory */     int  c,     /* character to store */     size_t size /* size of memory */ )</pre>                              |
| <b>DESCRIPTION</b>   | This routine stores <i>c</i> converted to an <b>unsigned char</b> in each of the elements of the array of <b>unsigned char</b> beginning at <i>m</i> , with size <i>size</i> . |
| <b>INCLUDE FILES</b> | <b>string.h</b>                                                                                                                                                                |
| <b>RETURNS</b>       | A pointer to <i>m</i> .                                                                                                                                                        |

## *memShow()*

**NAME** *memShow()* – show system memory partition blocks and statistics

**SYNOPSIS**

```
void memShow
(
 int type /* 1 = list all blocks in the free list */
)
```

**DESCRIPTION** This routine displays statistics about the available and allocated memory in the system memory partition. It shows the number of bytes, the number of blocks, and the average block size in both free and allocated memory, and also the maximum block size of free memory. It also shows the number of blocks currently allocated and the average allocated block size.

In addition, if *type* is 1, the routine displays a list of all the blocks in the free list of the system partition.

**EXAMPLE**

```
-> memShow 1
FREE LIST:
 num addr size
 ---- -
 1 0x3fee18 16
 2 0x3b1434 20
 3 0x4d188 2909400
SUMMARY:
status bytes blocks avg block max block

current
 free 2909436 3 969812 2909400
 alloc 969060 16102 60 -
cumulative
 alloc 1143340 16365 69 -
```

**RETURNS** N/A

**SEE ALSO** *memShow*, *memPartShow()*, *VxWorks Programmer's Guide: Target Shell*, **windsh**, *Tornado User's Guide: Shell*

## ***memShowInit()***

- NAME** *memShowInit()* – initialize the memory partition show facility
- SYNOPSIS** `void memShowInit (void)`
- DESCRIPTION** This routine links the memory partition show facility into the VxWorks system. These routines are included automatically when this show facility is configured into VxWorks using either of the following methods:
- If you use the configuration header files, define `INCLUDE_SHOW_ROUTINES` in `config.h`.
  - If you use the Tornado project facility, select `INCLUDE_MEM_SHOW`.
- RETURNS** N/A
- SEE ALSO** `memShow`
- 

## ***mib2ErrorAdd()***

- NAME** *mib2ErrorAdd()* – change a MIB-II error count
- SYNOPSIS** `STATUS mib2ErrorAdd`  
`(`  
`M2_INTERFACETBL * pMib,`  
`int              errCode,`  
`int              value`  
`)`
- DESCRIPTION** This function adds a specified value to one of the MIB-II error counters in a MIB-II interface table. The counter to be altered is specified by the `errCode` argument. Specifying a negative value reduces the error count, a positive value increases the error count.
- RETURNS** OK or ERROR.
- SEE ALSO** `endLib`

---

## *mib2Init()*

**NAME** *mib2Init()* – initialize a MIB-II structure

**SYNOPSIS**

```
STATUS mib2Init
(
 M2_INTERFACETBL * pMib, /* struct to be initialized */
 long ifType, /* ifType from m2Lib.h */
 UCHAR * phyAddr, /* MAC/PHY address */
 int addrLength, /* MAC/PHY address length */
 int mtuSize, /* MTU size */
 int speed /* interface speed */
)
```

**DESCRIPTION** Initialize a MIB-II structure. Set all error counts to zero. Assume a 10Mbps Ethernet device.

**RETURNS** OK or ERROR.

**SEE ALSO** *endLib*

---

## *mkdir()*

**NAME** *mkdir()* – make a directory

**SYNOPSIS**

```
STATUS mkdir
(
 char * dirName /* directory name */
)
```

**DESCRIPTION** This command creates a new directory in a hierarchical file system. The *dirName* string specifies the name to be used for the new directory, and can be either a full or relative pathname.

This call is supported by the VxWorks NFS and dosFs file systems.

**RETURNS** OK, or ERROR if the directory cannot be created.

**SEE ALSO** *usrLib, rmdir()*, *VxWorks Programmer's Guide: Target Shell*

| <b>NAME</b>          | <i>mktime()</i> – convert broken-down time into calendar time (ANSI)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>      | <pre>time_t mktime (     struct tm * timeptr /* pointer to broken-down structure */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b>   | <p>This routine converts the broken-down time, expressed as local time, in the structure pointed to by <i>timeptr</i> into a calendar time value with the same encoding as that of the values returned by the <i>time()</i> function. The original values of the <b>tm_wday</b> and <b>tm_yday</b> components of the <b>tm</b> structure are ignored, and the original values of the other components are not restricted to the ranges indicated in <b>time.h</b>. On successful completion, the values of <b>tm_wday</b> and <b>tm_yday</b> are set appropriately, and the other components are set to represent the specified calendar time, but with their values forced to the ranges indicated in <b>time.h</b>; the final value of <b>tm_mday</b> is not set until <b>tm_mon</b> and <b>tm_year</b> are determined.</p> |
| <b>INCLUDE FILES</b> | <b>time.h</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>RETURNS</b>       | The calendar time in seconds, or ERROR (-1) if calendar time cannot be calculated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>SYNOPSIS</b>    | <pre>STATUS mmuL64862DmaInit (     void * vrtBase, /* First valid DMA virtual address */     void * vrtTop, /* Last valid DMA virtual address */     UINT range /* range covered by I/O Page Table */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>This routine initializes the I/O MMU in the LSI Logic L64862 MBus to SBus Interface Chip (MS) for S-Bus DMA with the TI TMS390 SuperSPARC. It assumes <b>cacheLib</b> and <b>vmLib</b> have been initialized and that the TI TMS390 Processor MMU is enabled.</p> <p>It initializes the I/O MMU to map all valid virtual addresses <math>\geq</math> <i>vrtBase</i> and <math>\leq</math> <i>vrtTop</i>. It is usually called as follows:</p> <pre>(void)mmuL64862DmaInit ((void *) LOCAL_MEM_LOCAL_ADRS,                         (void *) (LOCAL_MEM_LOCAL_ADRS + LOCAL_MEM_SIZE - 1),                         IOMMU_IOC_R_RANGE);</pre> |
| <b>RETURNS</b>     | OK, or ERROR if the request cannot be satisfied.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SEE ALSO</b>    | <b>mmuL64862Lib</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## *mmuSparcRomInit()*

|             |                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME        | <i>mmuSparcRomInit()</i> – initialize the MMU for the ROM (SPARC)                                                                                                                                                                                                                                                                                                                                         |
| SYNOPSIS    | <pre>STATUS mmuSparcRomInit (     int * mmuTableAdrs, /* address for the MMU tables */     int mmuRomPhysAdrs, /* ROM physical address */     int romInitAdrs /* address where romInit was linked in */ )</pre>                                                                                                                                                                                           |
| DESCRIPTION | This routine initializes the MMU when the system is booted. It should be called only from <i>romInit()</i> . This routine is necessary because MMU libraries are not initialized by the boot code in bootConfig; they are initialized only in the VxWorks image in usrConfig. The same <b>sysPhysMemDesc</b> is used by this routine as well as <i>usrMmuInit()</i> in usrConfig to maintain consistency. |
| RETURNS     | OK.                                                                                                                                                                                                                                                                                                                                                                                                       |
| SEE ALSO    | <i>mmuSparcLib</i>                                                                                                                                                                                                                                                                                                                                                                                        |

---

## *modf()*

|                      |                                                                                                                                                                                              |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>modf()</i> – separate a floating-point number into integer and fraction parts (ANSI)                                                                                                      |
| <b>SYNOPSIS</b>      | <pre>double modf (     double value, /* value to split */     double * pIntPart /* where integer portion is stored */ )</pre>                                                                |
| <b>DESCRIPTION</b>   | This routine stores the integer portion of <i>value</i> in <i>pIntPart</i> and returns the fractional portion. Both parts are double precision and will have the same sign as <i>value</i> . |
| <b>INCLUDE FILES</b> | <b>math.h</b>                                                                                                                                                                                |
| <b>RETURNS</b>       | The double-precision fractional portion of <i>value</i> .                                                                                                                                    |
| <b>SEE ALSO</b>      | <b>ansiMath</b> , <i>frexp()</i> , <i>ldexp()</i>                                                                                                                                            |

| <b>NAME</b>        | <i>moduleCheck()</i> – verify checksums on all modules                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <pre>STATUS moduleCheck (     int options /* validation options */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>This routine verifies the checksums on the segments of all loaded modules. If any of the checksums are incorrect, a message is printed to the console, and the routine returns ERROR.</p> <p>By default, only the text segment checksum is validated.</p> <p>Bits in the <i>options</i> parameter may be set to control specific checks:</p> <p><b>MODCHECK_TEXT</b><br/>Validate the checksum for the TEXT segment (default).</p> <p><b>MODCHECK_DATA</b><br/>Validate the checksum for the DATA segment.</p> |

## ***moduleCreate()***

### **MODCHECK\_BSS**

Validate the checksum for the BSS segment.

### **MODCHECK\_NOPRINT**

Do not print a message (*moduleCheck()* still returns ERROR on failure.)

See the definitions in **moduleLib.h**

**RETURNS** OK, or ERROR if the checksum is invalid.

**SEE ALSO** **moduleLib**

---

## ***moduleCreate()***

**NAME** *moduleCreate()* – create and initialize a module

**SYNOPSIS**

```
MODULE_ID moduleCreate
(
 char * name, /* module name */
 int format, /* object module format */
 int flags /* symFlag as passed to loader (see loadModuleAt()) */
)
```

**DESCRIPTION** This routine creates an object module descriptor.

The arguments specify the name of the object module file, the object module format, and an argument specifying which symbols to add to the symbol table. See the *loadModuleAt()* description of *symFlag* for possible *flags* values.

Space for the new module is dynamically allocated.

**RETURNS** **MODULE\_ID**, or NULL if there is an error.

**SEE ALSO** **moduleLib**, *loadModuleAt()*

---

## *moduleCreateHookAdd()*

**NAME** *moduleCreateHookAdd()* – add a routine to be called when a module is added

**SYNOPSIS**

```
STATUS moduleCreateHookAdd
(
 FUNCPTR moduleCreateHookRtn /* routine called when module is added */
)
```

**DESCRIPTION** This routine adds a specified routine to a list of routines to be called when a module is created. The specified routine should be declared as follows:

```
void moduleCreateHook
(
 MODULE_ID moduleId /* the module ID */
)
```

This routine is called after all fields of the module ID have been filled in.

**NOTE** Modules do not have information about their object segments when they are created. This information is not available until after the entire load process has finished.

**RETURNS** OK or ERROR.

**SEE ALSO** *moduleLib, moduleCreateHookDelete()*

---

## *moduleCreateHookDelete()*

**NAME** *moduleCreateHookDelete()* – delete a previously added module create hook routine

**SYNOPSIS**

```
STATUS moduleCreateHookDelete
(
 FUNCPTR moduleCreateHookRtn /* routine called when module is added */
)
```

**DESCRIPTION** This routine removes a specified routine from the list of routines to be called at each *moduleCreate()* call.

**RETURNS** OK, or ERROR if the routine is not in the table of module create hook routines.

**SEE ALSO** *moduleLib, moduleCreateHookAdd()*

## ***moduleDelete()***

---

## *moduleFindByName()*

**NAME** *moduleFindByName()* – find a module by name

**SYNOPSIS**

```
MODULE_ID moduleFindByName
(
 char * moduleName /* name of module to find */
)
```

**DESCRIPTION** This routine searches for a module with a name matching *moduleName*.

**RETURNS** MODULE\_ID, or NULL if no match is found.

**SEE ALSO** **moduleLib**

---

## *moduleFindByNameAndPath()*

**NAME** *moduleFindByNameAndPath()* – find a module by file name and path

**SYNOPSIS**

```
MODULE_ID moduleFindByNameAndPath
(
 char * moduleName, /* file name to find */
 char * pathName /* path name to find */
)
```

**DESCRIPTION** This routine searches for a module with a name matching *moduleName* and path matching *pathName*.

**RETURNS** MODULE\_ID, or NULL if no match is found.

**SEE ALSO** **moduleLib**

## ***moduleFlagsGet()***

**NAME** *moduleFlagsGet()* – get the flags associated with a module ID

**SYNOPSIS**

```
int moduleFlagsGet
(
 MODULE_ID moduleId
)
```

**DESCRIPTION** This routine returns the flags associated with a module ID.

**RETURNS** The flags associated with the module ID, or NULL if the module ID is invalid.

**SEE ALSO** **moduleLib**

---

## ***moduleIdListGet()***

**NAME** *moduleIdListGet()* – get a list of loaded modules

**SYNOPSIS**

```
int moduleIdListGet
(
 MODULE_ID * idList, /* array of module IDs to be filled in */
 int maxModules /* max modules idList can accommodate */
)
```

**DESCRIPTION** This routine provides the calling task with a list of all loaded object modules. An unsorted list of module IDs for no more than *maxModules* modules is put into *idList*.

**RETURNS** The number of modules put into the ID list, or ERROR.

**SEE ALSO** **moduleLib**

---

## *moduleInfoGet()*

**NAME** *moduleInfoGet()* – get information about an object module

**SYNOPSIS**

```
STATUS moduleInfoGet
(
 MODULE_ID moduleId, /* module to return information about */
 MODULE_INFO * pModuleInfo /* pointer to module info struct */
)
```

**DESCRIPTION** This routine fills in a MODULE\_INFO structure with information about the specified module.

**RETURNS** OK or ERROR.

**SEE ALSO** *moduleLib*

---

## *moduleNameGet()*

**NAME** *moduleNameGet()* – get the name associated with a module ID

**SYNOPSIS**

```
char * moduleNameGet
(
 MODULE_ID moduleId
)
```

**DESCRIPTION** This routine returns a pointer to the name associated with a module ID.

**RETURNS** A pointer to the module name, or NULL if the module ID is invalid.

**SEE ALSO** *moduleLib*

## ***moduleSegFirst()***

- NAME** *moduleSegFirst()* – find the first segment in a module
- SYNOPSIS**
- ```
SEGMENT_ID moduleSegFirst  
(  
    MODULE_ID moduleId /* module to get segment from */  
)
```
- DESCRIPTION** This routine returns information about the first segment of a module descriptor.
- RETURNS** A pointer to the segment ID, or NULL if the segment list is empty.
- SEE ALSO** *moduleLib*, *moduleSegGet()*
-

moduleSegGet()

- NAME** *moduleSegGet()* – get (delete and return) the first segment from a module
- SYNOPSIS**
- ```
SEGMENT_ID moduleSegGet
(
 MODULE_ID moduleId /* module to get segment from */
)
```
- DESCRIPTION** This routine returns information about the first segment of a module descriptor, and then deletes the segment from the module.
- RETURNS** A pointer to the segment ID, or NULL if the segment list is empty.
- SEE ALSO** *moduleLib*, *moduleSegFirst()*

---

## *moduleSegNext()*

- NAME** *moduleSegNext()* – find the next segment in a module
- SYNOPSIS**
- ```
SEGMENT_ID moduleSegNext
(
    SEGMENT_ID segmentId /* segment whose successor is to be found */
)
```
- DESCRIPTION** This routine returns the segment in the list immediately following *segmentId*.
- RETURNS** A pointer to the segment ID, or NULL if there is no next segment.
- SEE ALSO** **moduleLib**

moduleShow()

- NAME** *moduleShow()* – show the current status for all the loaded modules
- SYNOPSIS**
- ```
STATUS moduleShow
(
 char * moduleNameOrId, /* name or ID of the module to show */
 int options /* display options */
)
```
- DESCRIPTION** This routine displays a list of the currently loaded modules and some information about where the modules are loaded.
- The specific information displayed depends on the format of the object modules. In the case of a.out and ECOFF object modules, *moduleShow()* displays the start of the text, data, and BSS segments.
- If *moduleShow()* is called with no arguments, a summary list of all loaded modules is displayed. It can also be called with an argument, *moduleNameOrId*, which can be either the name of a loaded module or a module ID. If it is called with either of these, more information about the specified module will be displayed.
- RETURNS** OK or ERROR.
- SEE ALSO** **moduleLib**, *VxWorks Programmer's Guide: Target Shell*, **windsh**, *Tornado User's Guide: Shell*

---

## **motCpmEndLoad()**

**NAME** *motCpmEndLoad()* – initialize the driver and device

**SYNOPSIS**

```
END_OBJ *motCpmEndLoad
(
 char * initString /* parameter string */
)
```

**DESCRIPTION** This routine initializes the driver and the device to the operational state. All of the device specific parameters are passed in the *initString*, which is of the following format:

*unit:motCpmAddr:ivec:sccNum:txBdNum:rxBdNum:txBdBase:rxBdBase:bufBase*

The parameters of this string are individually described in the **motCpmEnd** man page.

The SCC shares a region of memory with the driver. The caller of this routine can specify the address of a non-cacheable memory region with *bufBase*. Or, if this parameter is "NONE", the driver obtains this memory region by making calls to *cacheDmaMalloc()*. Non-cacheable memory space is important whenever the host processor uses cache memory. This is also the case when the MC68EN360 is operating in companion mode and is attached to a processor with cache memory.

After non-cacheable memory is obtained, this routine divides up the memory between the various buffer descriptors (BDs). The number of BDs can be specified by *txBdNum* and *rxBdNum*, or if "NULL", a default value of 32 BDs will be used. An additional number of buffers are reserved as receive loaner buffers. The number of loaner buffers is a default number of 16.

The user must specify the location of the transmit and receive BDs in the processor's dual ported RAM. *txBdBase* and *rxBdBase* give the offsets from *motCpmAddr* for the base of the BD rings. Each BD uses 8 bytes. Care must be taken so that the specified locations for Ethernet BDs do not conflict with other dual ported RAM structures.

Multiple individual device units are supported by this driver. Device units can reside on different chips, or could be on different SCCs within a single processor. The *sccNum* parameter is used to explicitly state which SCC is being used. SCC1 is most commonly used, thus this parameter most often equals "1".

Before this routine returns, it connects up the interrupt vector *ivec*.

**RETURNS** An END object pointer or NULL on error.

| <b>DESCRIPTION</b> | <p>This routine initializes both driver and device to an operational state using device specific parameters specified by <i>initString</i>.</p> <p>The parameter string, <i>initString</i>, is an ordered list of parameters each separated by a colon. The format of <i>initString</i> is:</p> <pre>"motCpmAddr:ivcc:bufBase:bufSize:fifoTxBase:fifoRxBase:tbdNum:rbdNum:phyAddr:isoPhyAddr: phyDefMode:userFlags"</pre> <p>The FEC shares a region of memory with the driver. The caller of this routine can specify the address of this memory region, or can specify that the driver must obtain this memory region from the system resources.</p> <p>A default number of transmit/receive buffer descriptors of 32 can be selected by passing zero in the parameters <i>tbdNum</i> and <i>rbdNum</i>. In other cases, the number of buffers selected should be greater than two.</p> <p>The <i>bufBase</i> parameter is used to inform the driver about the shared memory region. If this parameter is set to the constant "NONE," then this routine will attempt to allocate the shared memory from the system. Any other value for this parameter is interpreted by this routine as the address of the shared memory region to be used. The <i>bufSize</i> parameter is used to check that this region is large enough with respect to the provided values of both transmit/receive buffer descriptors.</p> <p>If the caller provides the shared memory region, then the driver assumes that this region does not require cache coherency operations, nor does it require conversions between virtual and physical addresses.</p> <p>If the caller indicates that this routine must allocate the shared memory region, then this routine will use <i>cacheDmaMalloc()</i> to obtain some cache-safe memory. The attributes of this memory will be checked, and if the memory is not write coherent, this routine will abort and return NULL.</p> |
| <b>RETURNS</b>     | an END object pointer, or NULL on error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## **mountdInit()**

**NAME** *mountdInit()* – initialize the mount daemon

**SYNOPSIS**

```
STATUS mountdInit
(
 int priority, /* priority of the mount daemon */
 int stackSize, /* stack size of the mount daemon */
 FUNCPTR authHook, /* hook to run to authorize each request */
 int nExports, /* maximum number of exported file systems */
 int options /* currently unused - set to 0 */
)
```

**DESCRIPTION** This routine spawns a mount daemon if one does not already exist. Defaults for the *priority* and *stackSize* arguments are in the global variables **mountdPriorityDefault** and **mountdStackSizeDefault**, and are initially set to MOUNTD\_PRIORITY\_DEFAULT and MOUNTD\_STACKSIZE\_DEFAULT respectively.

Normally, no authorization checking is performed by either mountd or nfsd. To add authorization checking, set *authHook* to point to a routine declared as follows:

```
nfsstat routine
(
 int progNum, /* RPC program number */
 int versNum, /* RPC program version number */
 int procNum, /* RPC procedure number */
 struct sockaddr_in clientAddr, /* address of the client */
 MOUNTD_ARGUMENT * mountdArg /* argument of the call */
)
```

The *authHook* callback must return OK if the request is authorized, and any defined NFS error code (usually NFSERR\_ACCES) if not.

**RETURNS** OK, or ERROR if the mount daemon could not be correctly initialized.

| <b>NAME</b>        | <i>mq_close()</i> – close a message queue (POSIX)                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <pre>int mq_close (     mqd_t mqdes /* message queue descriptor */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | This routine is used to indicate that the calling task is finished with the specified message queue <i>mqdes</i> . The <i>mq_close()</i> call deallocates any system resources allocated by the system for use by this task for its message queue. The behavior of a task that is blocked on either a <i>mq_send()</i> or <i>mq_receive()</i> is undefined when <i>mq_close()</i> is called. The <i>mqdes</i> parameter will no longer be a valid message queue ID. |
| <b>RETURNS</b>     | 0 (OK) if the message queue is closed successfully, otherwise -1 (ERROR).                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ERRNO</b>       | EBADF                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>mq_getattr()</i> – get message queue attributes (POSIX)                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <pre>int mq_getattr (     mqd_t          mqdes, /* message queue descriptor */     struct mq_attr * pMqStat /* buffer in which to return attributes */ )</pre>                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | This routine gets status information and attributes associated with a specified message queue <i>mqdes</i> . Upon return, the following members of the <b>mq_attr</b> structure referenced by <i>pMqStat</i> will contain the values set when the message queue was created but with modifications made by subsequent calls to <i>mq_setattr()</i> : |
|                    | <p><b>mq_flags</b><br/>May be modified by <i>mq_setattr()</i>.</p> <p>The following were set at message queue creation:</p> <p><b>mq_maxmsg</b><br/>Maximum number of messages.</p>                                                                                                                                                                  |

**mq\_msgsize**

Maximum message size.

**mq\_curmsgs**

The number of messages currently in the queue.

**RETURNS** 0 (OK) if message attributes can be determined, otherwise -1 (ERROR).**ERRNO** EBADF**SEE ALSO** *mqPxBLib, mq\_open(), mq\_send(), mq\_setattr()*

## *mq\_notify()*

**NAME** *mq\_notify()* – notify a task that a message is available on a queue (POSIX)

**SYNOPSIS**

```
int mq_notify
(
 mqd_t mqdes, /* message queue descriptor */
 const struct sigevent * pNotification /* real-time signal */
)
```

**DESCRIPTION** If *pNotification* is not NULL, this routine attaches the specified *pNotification* request by the calling task to the specified message queue *mqdes* associated with the calling task. The real-time signal specified by *pNotification* will be sent to the task when the message queue changes from empty to non-empty. If a task has already attached a notification request to the message queue, all subsequent attempts to attach a notification to the message queue will fail. A task is able to attach a single notification to each *mqdes* it has unless another task has already attached one.

If *pNotification* is NULL and the task has previously attached a notification request to the message queue, the attached notification request is detached and the queue is available for another task to attach a notification request.

If a notification request is attached to a message queue and any task is blocked in *mq\_receive()* waiting to receive a message when a message arrives at the queue, then the appropriate *mq\_receive()* will be completed and the notification request remains pending.

**RETURNS** 0 (OK) if successful, otherwise -1 (ERROR).**ERRNO** EBADF, EBUSY, EINVAL**SEE ALSO** *mqPxBLib, mq\_open(), mq\_send()*

---

## **mq\_open()**

**NAME** `mq_open()` – open a message queue (POSIX)

**SYNOPSIS**

```
mqd_t mq_open
(
 const char * mqName, /* name of queue to open */
 int oflags /* open flags */
)
```

**DESCRIPTION** This routine establishes a connection between a named message queue and the calling task. After a call to `mq_open()`, the task can reference the message queue using the address returned by the call. The message queue remains usable until the queue is closed by a successful call to `mq_close()`.

The *oflags* argument controls whether the message queue is created or merely accessed by the `mq_open()` call. The following flag bits can be set in *oflags*:

**O\_RDONLY**

Open the message queue for receiving messages. The task can use the returned message queue descriptor with `mq_receive()`, but not `mq_send()`.

**O\_WRONLY**

Open the message queue for sending messages. The task can use the returned message queue descriptor with `mq_send()`, but not `mq_receive()`.

**O\_RDWR**

Open the queue for both receiving and sending messages. The task can use any of the functions allowed for **O\_RDONLY** and **O\_WRONLY**.

Any combination of the remaining flags can be specified in *oflags*:

**O\_CREAT**

This flag is used to create a message queue if it does not already exist. If **O\_CREAT** is set and the message queue already exists, then **O\_CREAT** has no effect except as noted below under **O\_EXCL**. Otherwise, `mq_open()` creates a message queue. The **O\_CREAT** flag requires a third and fourth argument: *mode*, which is of type `mode_t`, and *pAttr*, which is of type pointer to an `mq_attr` structure. The value of *mode* has no effect in this implementation. If *pAttr* is NULL, the message queue is created with implementation-defined default message queue attributes. If *pAttr* is non-NULL, the message queue attributes `mq_maxmsg` and `mq_msgsize` are set to the values of the corresponding members in the `mq_attr` structure referred to by *pAttr*; if either attribute is less than or equal to zero, an error is returned and `errno` is set to `EINVAL`.

**O\_EXCL**

This flag is used to test whether a message queue already exists. If **O\_EXCL** and **O\_CREAT** are set, `mq_open()` fails if the message queue name exists.

**O\_NONBLOCK**

The setting of this flag is associated with the open message queue descriptor and determines whether a *mq\_send()* or *mq\_receive()* will wait for resources or messages that are not currently available, or fail with *errno* set to *EAGAIN*.

The *mq\_open()* call does not add or remove messages from the queue.

**NOTE**

Some POSIX functionality is not yet supported:

- A message queue cannot be closed with calls to *\_exit()* or *exec()*.
- A message queue cannot be implemented as a file.
- Message queue names will not appear in the file system.

**RETURNS**

A message queue descriptor, otherwise -1 (ERROR).

**ERRNO**

*EEXIST*, *EINVAL*, *ENOENT*, *ENOSPC*

**SEE ALSO**

*mqPxLib*, *mq\_send()*, *mq\_receive()*, *mq\_close()*, *mq\_setattr()*, *mq\_getattr()*, *mq\_unlink()*

---

## *mq\_receive()*

**NAME**

*mq\_receive()* – receive a message from a message queue (POSIX)

**SYNOPSIS**

```
ssize_t mq_receive
(
 mqd_t mqdes, /* message queue descriptor */
 void * pMsg, /* buffer to receive message */
 size_t msgLen, /* size of buffer, in bytes */
 int * pMsgPrio /* if not NULL, priority of message */
)
```

**DESCRIPTION**

This routine receives the oldest of the highest priority message from the message queue specified by *mqdes*. If the size of the buffer in bytes, specified by the *msgLen* argument, is less than the *mq\_msgsize* attribute of the message queue, *mq\_receive()* will fail and return an error. Otherwise, the selected message is removed from the queue and copied to *pMsg*.

If *pMsgPrio* is not NULL, the priority of the selected message will be stored in *pMsgPrio*.

If the message queue is empty and *O\_NONBLOCK* is not set in the message queue's description, *mq\_receive()* will block until a message is added to the message queue, or until it is interrupted by a signal. If more than one task is waiting to receive a message when a message arrives at an empty queue, the task of highest priority that has been waiting the longest will be selected to receive the message. If the specified message queue

***mq\_send()***

is empty and `O_NONBLOCK` is set in the message queue's description, no message is removed from the queue, and `mq_receive()` returns an error.

|                 |                                                                    |
|-----------------|--------------------------------------------------------------------|
| <b>RETURNS</b>  | The length of the selected message in bytes, otherwise -1 (ERROR). |
| <b>ERRNO</b>    | EAGAIN, EBADF, EMSGSIZE, EINTR                                     |
| <b>SEE ALSO</b> | <code>mqPxLib</code> , <code>mq_send()</code>                      |

---

## ***mq\_send()***

**NAME** `mq_send()` – send a message to a message queue (POSIX)

**SYNOPSIS**

```
int mq_send
(
 mqd_t mqdes, /* message queue descriptor */
 const void * pMsg, /* message to send */
 size_t msgLen, /* size of message, in bytes */
 int msgPrio /* priority of message */
)
```

**DESCRIPTION** This routine adds the message `pMsg` to the message queue `mqdes`. The `msgLen` parameter specifies the length of the message in bytes pointed to by `pMsg`. The value of `pMsg` must be less than or equal to the `mq_msgsize` attribute of the message queue, or `mq_send()` will fail.

If the message queue is not full, `mq_send()` will behave as if the message is inserted into the message queue at the position indicated by the `msgPrio` argument. A message with a higher numeric value for `msgPrio` is inserted before messages with a lower value. The value of `msgPrio` must be less than or equal to 31.

If the specified message queue is full and `O_NONBLOCK` is not set in the message queue's, `mq_send()` will block until space becomes available to queue the message, or until it is interrupted by a signal. The priority scheduling option is supported in the event that there is more than one task waiting on space becoming available. If the message queue is full and `O_NONBLOCK` is set in the message queue's description, the message is not queued, and `mq_send()` returns an error.

### **USE BY INTERRUPT SERVICE ROUTINES**

This routine can be called by interrupt service routines as well as by tasks. This is one of the primary means of communication between an interrupt service routine and a task. If `mq_send()` is called from an interrupt service routine, it will behave as if the `O_NONBLOCK` flag were set.

**RETURNS** 0 (OK), otherwise -1 (ERROR).

**ERRNO** EAGAIN, EBADF, EINTR, EINVAL, EMSGSIZE

**SEE ALSO** mqPxLib, mq\_receive()

---

## **mq\_setattr()**

**NAME** *mq\_setattr()* – set message queue attributes (POSIX)

**SYNOPSIS**

```
int mq_setattr
(
 mqd_t mqdes, /* message queue descriptor */
 const struct mq_attr * pMqStat, /* new attributes */
 struct mq_attr * pOldMqStat /* old attributes */
)
```

**DESCRIPTION** This routine sets attributes associated with the specified message queue *mqdes*. The message queue attributes corresponding to the following members defined in the **mq\_attr** structure are set to the specified values upon successful completion of the call:

### **mq\_flags**

The value the **O\_NONBLOCK** flag.

If *pOldMqStat* is non-NULL, *mq\_setattr()* will store, in the location referenced by *pOldMqStat*, the previous message queue attributes and the current queue status. These values are the same as would be returned by a call to *mq\_getattr()* at that point.

**RETURNS** 0 (OK) if attributes are set successfully, otherwise -1 (ERROR).

**ERRNO** EBADF

**SEE ALSO** mqPxLib, mq\_open(), mq\_send(), mq\_getattr()

**mq\_unlink()**

---

**mq\_unlink()****NAME** *mq\_unlink()* – remove a message queue (POSIX)**SYNOPSIS**  

```
int mq_unlink
(
 const char * mqName /* name of message queue */
)
```

**DESCRIPTION** This routine removes the message queue named by the pathname *mqName*. After a successful call to *mq\_unlink()*, a call to *mq\_open()* on the same message queue will fail if the flag **O\_CREAT** is not set. If one or more tasks have the message queue open when *mq\_unlink()* is called, removal of the message queue is postponed until all references to the message queue have been closed.**RETURNS** 0 (OK) if the message queue is unlinked successfully, otherwise -1 (ERROR).**ERRNO** ENOENT**SEE ALSO** *mqPxLib*, *mq\_close()*, *mq\_open()*

---

**mRegs()****NAME** *mRegs()* – modify registers**SYNOPSIS**  

```
STATUS mRegs
(
 char * regName, /* register name, NULL for all */
 int taskNameOrId /* task name or task ID, 0 = default task */
)
```

**DESCRIPTION** This command modifies the specified register for the specified task. If *taskNameOrId* is omitted or zero, the last task referenced is assumed. If the specified register is not found, it prints out the valid register list and returns ERROR. If no register is specified, it sequentially prompts the user for new values for a task's registers. It displays each register and the current contents of that register, in turn. The user can respond in one of several ways:**RETURN**

Do not change this register, but continue, prompting at the next register.

*number*

Set this register to *number*.

. (dot)

Do not change this register, and quit.

EOF

Do not change this register, and quit.

All numbers are entered and displayed in hexadecimal, except floating-point values, which may be entered in double precision.

**RETURNS** OK, or ERROR if the task or register does not exist.

**SEE ALSO** **usrLib**, **m()**, *VxWorks Programmer's Guide: Target Shell*, **windsh**, *Tornado User's Guide: Shell*

---

## **mRouteAdd()**

**NAME** *mRouteAdd()* – add multiple routes to the same destination

**SYNOPSIS** **STATUS** *mRouteAdd*

```
(
 char * pDest, /* destination addr in internet dot notation */
 char * pGate, /* gateway address in internet dot notation */
 long mask, /* mask for destination */
 int tos, /* type of service */
 int flags /* route flags */
)
```

**DESCRIPTION** This routine is similar to *routeAdd()*, except that you can use multiple *mRouteAdd()* calls to add multiple routes to the same location. Use *pDest* to specify the destination, *pGate* to specify the gateway to that destination, *mask* to specify destination mask, and *tos* to specify the type of service. For *tos*, **netinet/ip.h** defines the following constants as valid values:

```
 IPTOS_LOWDELAY
 IPTOS_THROUGHPUT
 IPTOS_RELIABILITY
 IPTOS_MINCOST
```

Use *flags* to specify any flags you want to associate with this entry. The valid non-zero values are **RTF\_HOST** and **RTF\_CLONING** defined in **net/route.h**.

**EXAMPLE** To add a route to the 90.0.0.0 network through 91.0.0.3:

***mRouteDelete()***

```
-> mRouteAdd ("90.0.0.0", "91.0.0.3", 0xffffffff00, 0, 0);
```

Using *mRouteAdd()*, you could create multiple routes to the same destination. VxWorks would distinguish among these routes based on factors such as the netmask or the type of service. Thus, it is perfectly legal to say:

```
-> mRouteAdd ("90.0.0.0", "91.0.0.3", 0xffffffff00, 0, 0);
-> mRouteAdd ("90.0.0.0", "91.0.0.254", 0xffff0000, 0, 0);
```

This adds two routes to the same network, "90.0.0.0", that go by two different gateways. The differentiating factor is the netmask.

This routine adds a route of type **M2\_ipRouteProto\_other**, which is a static route. This route will not be modified or deleted until a call to *mRouteDelete()* removes it.

**RETURNS**

OK or ERROR.

**SEE ALSO**

*routeLib*, *mRouteEntryAdd()*, *mRouteDelete()*, *routeAdd()*

---

## *mRouteDelete()*

**NAME**

*mRouteDelete()* – delete a route from the routing table

**SYNOPSIS**

```
STATUS mRouteDelete
(
 char * pDest, /* destination address */
 long mask, /* mask for destination */
 int tos, /* type of service */
 int flags /* either 0 or RTF_HOST */
)
```

**DESCRIPTION**

This routine deletes a routing table entry as specified by the destination, *pDest*, the destination mask, *mask*, and type of service, *tos*. The *tos* values are as defined in the reference entry for *mRouteAdd()*.

**EXAMPLE**

Consider the case of a route added in the following manner:

```
-> mRouteAdd ("90.0.0.0", "91.0.0.3", 0xffffffff00, 0, 0);
```

To delete a route that was added in the above manner, call *mRouteDelete()* as follows:

```
-> mRouteDelete("90.0.0.0", 0xffffffff00, 0);
```

If the netmask and or type of service do not match, the route is not deleted.

The value of *flags* should be *RTF\_HOST* for host routes, *RTF\_CLONING* for routes which need to be cloned, and 0 in all other cases.

**RETURNS** OK or ERROR.

**SEE ALSO** routeLib, mRouteAdd()

---

## *mRouteEntryAdd()*

**NAME** *mRouteEntryAdd()* – add a protocol-specific route to the routing table

**SYNOPSIS**

```
STATUS mRouteEntryAdd
(
 long destIp, /* destination address, network order */
 long gateIp, /* gateway address, network order */
 long mask, /* mask for destination, network order */
 int tos, /* type of service */
 int flags, /* route flags */
 int proto /* routing protocol */
)
```

**DESCRIPTION** For a single destination *destIp*, this routine can add additional routes *gateIp* to the routing table. The different routes are distinguished by a destination mask *mask*, the type of service *tos*, and associated flag values *flags*. Valid values for *flags* are 0, **RTF\_HOST**, **RTF\_CLONING** (defined in **net/route.h**). The *proto* parameter identifies the protocol that generated this route. Values for *proto* may be found in **m2Lib.h**. The *tos* parameter takes one of following values (defined in **netinet/ip.h**):

```
 IPTOS_LOWDELAY
 IPTOS_THROUGHPUT
 IPTOS_RELIABILITY
 IPTOS_MINCOST
```

**RETURNS** OK or ERROR.

**SEE ALSO** routeLib, m2Lib.h, mRouteAdd(), mRouteDelete()

---

## **mRouteEntryDelete()**

**NAME** *mRouteEntryDelete()* – delete route from the routing table

**SYNOPSIS**

```
STATUS mRouteEntryDelete
(
 long destIp, /* destination address, network order */
 long gateIp, /* gateway address, network order */
 long mask, /* mask for destination, network order */
 int tos, /* type of service */
 int flags, /* route flags */
 int proto /* routing protocol */
)
```

**DESCRIPTION** This routine deletes a protocol-specific route from the routing table. Specify the route using a destination *pDest*, a gateway *pGate*, a destination mask *mask*, the type of service *tos*, a *flags* value, and a *proto* value that identifies the routing protocol that added the route. The valid values for *flags* are 0 and **RTF\_HOST** (defined in **net/route.h**). Values for *proto* may be found in **m2Lib.h** and *tos* is one of the following values defined in **netinet/ip.h**:

```
 IPTOS_LOWDELA
 IPTOS_THROUGHPU
 IPTOS_RELIABILIT
 IPTOS_MINCOST
```

An existing route is deleted only if it is owned by the protocol specified by *proto*.

**RETURNS** OK or ERROR.

**SEE ALSO** **routeLib**

---

## **mRouteShow()**

**NAME** *mRouteShow()* – print the entries of the routing table

**SYNOPSIS**

```
void mRouteShow
(
)
```

**DESCRIPTION** This routine prints the route entries in the routing table.

**RETURNS** N/A

**SEE ALSO** netShow

---

## *msgQCreate()*

**NAME** *msgQCreate()* – create and initialize a message queue

**SYNOPSIS**

```
MSG_Q_ID msgQCreate
(
 int maxMsgs, /* max messages that can be queued */
 int maxMsgLength, /* max bytes in a message */
 int options /* message queue options */
)
```

**DESCRIPTION** This routine creates a message queue capable of holding up to *maxMsgs* messages, each up to *maxMsgLength* bytes long. The routine returns a message queue ID used to identify the created message queue in all subsequent calls to routines in this library. The queue can be created with the following options:

**MSG\_Q\_FIFO** (0x00)  
queue pending tasks in FIFO order.

**MSG\_Q\_PRIORITY** (0x01)  
queue pending tasks in priority order.

**RETURNS** *MSG\_Q\_ID*, or NULL if error.

**ERRNO** *S\_memLib\_NOT\_ENOUGH\_MEMORY*, *S\_intLib\_NOT\_ISR\_CALLABLE*

**SEE ALSO** *msgQLib*, *msgQSmLib*

---

## *msgQDelete()*

**NAME** *msgQDelete()* – delete a message queue

**SYNOPSIS**

```
STATUS msgQDelete
(
 MSG_Q_ID msgQId /* message queue to delete */
)
```

**msgQInfoGet()**

|                    |                                                                                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | This routine deletes a message queue. Any task blocked on either a <i>msgQSend()</i> or <i>msgQReceive()</i> will be unblocked and receive an error from the call with <b>errno</b> set to <b>S_objLib_OBJECT_DELETED</b> . The <i>msgQId</i> parameter will no longer be a valid message queue ID. |
| <b>RETURNS</b>     | OK or ERROR.                                                                                                                                                                                                                                                                                        |
| <b>ERRNO</b>       | S_objLib_OBJ_ID_ERROR, S_intLib_NOT_ISR_CALLABLE                                                                                                                                                                                                                                                    |
| <b>SEE ALSO</b>    | msgQLib, msgQSmLib                                                                                                                                                                                                                                                                                  |

**msgQInfoGet()**

**NAME** *msgQInfoGet()* – get information about a message queue

**SYNOPSIS**

```
STATUS msgQInfoGet
(
 MSG_Q_ID msgQId, /* message queue to query */
 MSG_Q_INFO * pInfo /* where to return msg info */
)
```

**DESCRIPTION** This routine gets information about the state and contents of a message queue. The parameter *pInfo* is a pointer to a structure of type **MSG\_Q\_INFO** defined in **msgQLib.h** as follows:

```
typedef struct /* MSG_Q_INFO */
{
 int numMsgs; /* OUT: number of messages queued */
 int numTasks; /* OUT: number of tasks waiting on msg q */
 int sendTimeouts; /* OUT: count of send timeouts */
 int rcvTimeouts; /* OUT: count of receive timeouts */
 int options; /* OUT: options with which msg q was created */
 int maxMsgs; /* OUT: max messages that can be queued */
 int maxMsgLength; /* OUT: max byte length of each message */
 int taskIdListMax; /* IN: max tasks to fill in taskIdList */
 int * taskIdList; /* PTR: array of task IDs waiting on msg q */
 int msgListMax; /* IN: max msgs to fill in msg lists */
 char ** msgPtrList; /* PTR: array of msg ptrs queued to msg q */
 int * msgLenList; /* PTR: array of lengths of msgs */
} MSG_Q_INFO;
```

If a message queue is empty, there may be tasks blocked on receiving. If a message queue is full, there may be tasks blocked on sending. This can be determined as follows:

- If *numMsgs* is 0, then *numTasks* indicates the number of tasks blocked on receiving.
- If *numMsgs* is equal to *maxMsgs*, then *numTasks* is the number of tasks blocked on sending.
- If *numMsgs* is greater than 0 but less than *maxMsgs*, then *numTasks* will be 0.

A list of pointers to the messages queued and their lengths can be obtained by setting *msgPtrList* and *msgLenList* to the addresses of arrays to receive the respective lists, and setting *msgListMax* to the maximum number of elements in those arrays. If either list pointer is NULL, no data will be returned for that array.

No more than *msgListMax* message pointers and lengths are returned, although *numMsgs* will always be returned with the actual number of messages queued.

For example, if the caller supplies a *msgPtrList* and *msgLenList* with room for 10 messages and sets *msgListMax* to 10, but there are 20 messages queued, then the pointers and lengths of the first 10 messages in the queue are returned in *msgPtrList* and *msgLenList*, but *numMsgs* will be returned with the value 20.

A list of the task IDs of tasks blocked on the message queue can be obtained by setting *taskIdList* to the address of an array to receive the list, and setting *taskIdListMax* to the maximum number of elements in that array. If *taskIdList* is NULL, then no task IDs are returned. No more than *taskIdListMax* task IDs are returned, although *numTasks* will always be returned with the actual number of tasks blocked.

For example, if the caller supplies a *taskIdList* with room for 10 task IDs and sets *taskIdListMax* to 10, but there are 20 tasks blocked on the message queue, then the IDs of the first 10 tasks in the blocked queue will be returned in *taskIdList*, but *numTasks* will be returned with the value 20.

Note that the tasks returned in *taskIdList* may be blocked for either send or receive. As noted above this can be determined by examining *numMsgs*.

The variables *sendTimeouts* and *recvTimeouts* are the counts of the number of times *msgQSend()* and *msgQReceive()* respectively returned with a timeout.

The variables *options*, *maxMsgs*, and *maxMsgLength* are the parameters with which the message queue was created.

**WARNING**

The information returned by this routine is not static and may be obsolete by the time it is examined. In particular, the lists of task IDs and/or message pointers may no longer be valid. However, the information is obtained atomically, thus it will be an accurate snapshot of the state of the message queue at the time of the call. This information is generally used for debugging purposes only.

**WARNING**

The current implementation of this routine locks out interrupts while obtaining the information. This can compromise the overall interrupt latency of the system. Generally this routine is used for debugging purposes only.

**RETURNS** OK or ERROR.

**ERRNO** S\_distLib\_NOT\_INITIALIZED, S\_smObjLib\_NOT\_INITIALIZED, S\_objLib\_OBJ\_ID\_ERROR

**SEE ALSO** msgQShow

---

## ***msgQNumMsgs()***

**NAME** *msgQNumMsgs()* – get the number of messages queued to a message queue

**SYNOPSIS**

```
int msgQNumMsgs
(
 MSG_Q_ID msgQId /* message queue to examine */
)
```

**DESCRIPTION** This routine returns the number of messages currently queued to a specified message queue.

**RETURNS** The number of messages queued, or ERROR.

**ERRNO** S\_distLib\_NOT\_INITIALIZED, S\_smObjLib\_NOT\_INITIALIZED, S\_objLib\_OBJ\_ID\_ERROR

**SEE ALSO** msgQLib, msgQSmLib

---

## ***msgQReceive()***

**NAME** *msgQReceive()* – receive a message from a message queue

**SYNOPSIS**

```
int msgQReceive
(
 MSG_Q_ID msgQId, /* message queue from which to receive */
 char * buffer, /* buffer to receive message */
 UINT maxNBytes, /* length of buffer */
 int timeout /* ticks to wait */
)
```

**DESCRIPTION** This routine receives a message from the message queue *msgQId*. The received message is copied into the specified *buffer*, which is *maxNBytes* in length. If the message is longer

than *maxNBytes*, the remainder of the message is discarded (no error indication is returned).

The *timeout* parameter specifies the number of ticks to wait for a message to be sent to the queue, if no message is available when *msgQReceive()* is called. The *timeout* parameter can also have the following special values:

**NO\_WAIT** (0)

return immediately, even if the message has not been sent.

**WAIT\_FOREVER** (-1)

never time out.

|                 |                                                                                                                                                                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>WARNING</b>  | This routine must not be called by interrupt service routines.                                                                                                                                                                          |

## *msgQSend()*

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>msgQSend()</i> – send a message to a message queue                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <pre> STATUS msgQSend (     MSG_Q_ID msgQId, /* message queue on which to send */     char *   buffer, /* message to send */     UINT     nBytes, /* length of message */     int      timeout, /* ticks to wait */     int      priority /* MSG_PRI_NORMAL or MSG_PRI_URGENT */ ) </pre>                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>This routine sends the message in <i>buffer</i> of length <i>nBytes</i> to the message queue <i>msgQId</i>. If any tasks are already waiting to receive messages on the queue, the message will immediately be delivered to the first waiting task. If no task is waiting to receive messages, the message is saved in the message queue.</p> <p>The <i>timeout</i> parameter specifies the number of ticks to wait for free space if the message queue is full. The <i>timeout</i> parameter can also have the following special values:</p> |

**NO\_WAIT** (0)  
return immediately, even if the message has not been sent.

**WAIT\_FOREVER** (-1)  
never time out.

The *priority* parameter specifies the priority of the message being sent. The possible values are:

**MSG\_PRI\_NORMAL** (0)  
normal priority; add the message to the tail of the list of queued messages.

**MSG\_PRI\_URGENT** (1)  
urgent priority; add the message to the head of the list of queued messages.

#### USE BY INTERRUPT SERVICE ROUTINES

This routine can be called by interrupt service routines as well as by tasks. This is one of the primary means of communication between an interrupt service routine and a task. When called from an interrupt service routine, *timeout* must be **NO\_WAIT**.

**RETURNS** OK or ERROR.

**ERRNO** S\_distLib\_NOT\_INITIALIZED, S\_objLib\_OBJ\_ID\_ERROR, S\_objLib\_OBJ\_DELETED, S\_objLib\_OBJ\_UNAVAILABLE, S\_objLib\_OBJ\_TIMEOUT, S\_msgQLib\_INVALID\_MSG\_LENGTH, S\_msgQLib\_NON\_ZERO\_TIMEOUT\_AT\_INT\_LEVEL

**SEE ALSO** msgQLib, msgQSmLib

---

## msgQShow()

**NAME** msgQShow() – show information about a message queue

**SYNOPSIS**

```
STATUS msgQShow
(
 MSG_Q_ID msgQId, /* message queue to display */
 int level /* 0 = summary, 1 = details */
)
```

**DESCRIPTION** This routine displays the state and optionally the contents of a message queue. A summary of the state of the message queue is displayed as follows:

```
Message Queue Id : 0x3f8c20
Task Queuing : FIFO
Message Byte Len : 150
```

```

Messages Max : 50
Messages Queued : 0
Receivers Blocked : 1
Send timeouts : 0
Receive timeouts : 0

```

If *level* is 1, then more detailed information will be displayed. If messages are queued, they will be displayed as follows:

```

Messages queued:
address length value
1 0x123eb204 4 0x00000001 0x12345678

```

If tasks are blocked on the queue, they will be displayed as follows:

```

Receivers blocked:
NAME TID PRI DELAY

tExcTask 3fd678 0 21

```

- RETURNS**           OK or ERROR.
- ERRNO**            S\_distLib\_NOT\_INITIALIZED, S\_smObjLib\_NOT\_INITIALIZED
- SEE ALSO**          **msgQShow**, *VxWorks Programmer's Guide: Target Shell*, **windsh**, *Tornado User's Guide: Shell*

## *msgQShowInit()*

- NAME**            *msgQShowInit()* – initialize the message queue show facility
- SYNOPSIS**        **void msgQShowInit (void)**
- DESCRIPTION**    This routine links the message queue show facility into the VxWorks system. It is called automatically when the message queue show facility is configured into VxWorks using either of the following methods:
  - If you use the configuration header files, define **INCLUDE\_SHOW\_ROUTINES** in **config.h**.
  - If you use the Tornado project facility, select **INCLUDE\_MSG\_Q\_SHOW**.
- RETURNS**        N/A
- SEE ALSO**        **msgQShow**

---

## *msgQSmCreate()*

**NAME** *msgQSmCreate()* – create and initialize a shared memory message queue (VxMP Opt.)

**SYNOPSIS**

```
MSG_Q_ID msgQSmCreate
(
 int maxMsgs, /* max messages that can be queued */
 int maxMsgLength, /* max bytes in a message */
 int options /* message queue options */
)
```

**DESCRIPTION** This routine creates a shared memory message queue capable of holding up to *maxMsgs* messages, each up to *maxMsgLength* bytes long. It returns a message queue ID used to identify the created message queue. The queue can only be created with the option `MSG_Q_FIFO` (0), thus queuing pending tasks in FIFO order.

The global message queue identifier returned can be used directly by generic message queue handling routines in `msgQLib` -- *msgQSend()*, *msgQReceive()*, and *msgQNumMsgs()* -- and by the show routines *show()* and *msgQShow()*.

If there is insufficient memory to store the message queue structure in the shared memory message queue partition or if the shared memory system pool cannot handle the requested message queue size, shared memory message queue creation will fail with **errno** set to `S_memLib_NOT_ENOUGH_MEMORY`. This problem can be solved by incrementing the value of `SM_OBJ_MAX_MSG_Qand`/or the shared memory objects dedicated memory size `SM_OBJ_MEM_SIZE`.

Before this routine can be called, the shared memory objects facility must be initialized (see `msgQSmLib`).

**AVAILABILITY** This routine is distributed as a component of the unbundled shared memory objects support option, VxMP.

**RETURNS** `MSG_Q_ID`, or NULL if error.

**ERRNO** `S_memLib_NOT_ENOUGH_MEMORY`, `S_intLib_NOT_ISR_CALLABLE`,  
`S_msgQLib_INVALID_QUEUE_TYPE`, `S_smObjLib_LOCK_TIMEOUT`

**SEE ALSO** `msgQSmLib`, `smObjLib`, `msgQLib`, `msgQShow`

---

## *munlock()*

**NAME** *munlock()* – unlock specified pages (POSIX)

**SYNOPSIS**

```
int munlock
(
 const void * addr,
 size_t len
)
```

**DESCRIPTION** This routine unlocks specified pages from being memory resident.

**RETURNS** 0 (OK) always.

**ERRNO** N/A

**SEE ALSO** *mmanPxLib*

---

## *munlockall()*

**NAME** *munlockall()* – unlock all pages used by a process (POSIX)

**SYNOPSIS**

```
int munlockall (void)
```

**DESCRIPTION** This routine unlocks all pages used by a process from being memory resident.

**RETURNS** 0 (OK) always.

**ERRNO** N/A

**SEE ALSO** *mmanPxLib*

---

## ***muxAddressForm()***

**NAME** *muxAddressForm()* – form an address into a packet

**SYNOPSIS**

```
M_BLK_ID muxAddressForm
(
 void* pCookie, /* cookie that identifies the device */
 M_BLK_ID pMblk, /* structure to contain packet */
 M_BLK_ID pSrcAddr, /* structure containing source address */
 M_BLK_ID pDstAddr /* structure containing destination address */
)
```

**DESCRIPTION** This routine accepts the source and destination addressing information through the *pSrcAddr* and *pDstAddr* mBlks and returns an **M\_BLK\_ID** that points to the assembled link-level header. This routine prepends the link-level header into *pMblk* if there is enough space available or it allocates a new **mBlk-clBlk**-cluster and prepends the new *mBlk* to the **mBlk** chain passed in *pMblk*. This routine returns a pointer to an **mBlk** that contains the link-level header information.

*pCookie*

Expects the pointer returned from the *muxBind()*. This pointer identifies the device to which the MUX has bound this protocol.

*pMblk*

Expects a pointer to the **mBlk** structure that contains the packet.

*pSrcAddr*

Expects a pointer to the **mBlk** that contains the source address.

*pDstAddr*

Expects a pointer to the **mBlk** that contains the destination address.

**RETURNS** **M\_BLK\_ID** or **NULL**.

**ERRNO** **S\_muxLib\_NO\_DEVICE**

**SEE ALSO** **muxLib**

---

## *muxAddrResFuncAdd()*

**NAME** *muxAddrResFuncAdd()* – add an address resolution function

**SYNOPSIS**

```
STATUS muxAddrResFuncAdd
(
 long ifType, /* Media interface type from m2Lib.h */
 long protocol, /* Protocol type from RFC 1700 */
 FUNCPTR addrResFunc /* Function to call. */
)
```

**DESCRIPTION** This routine takes an *ifType* from **m2Lib.h**, a protocol number from RFC 1700 and a pointer to an address resolution function and installs that function for later retrieval by *muxAddrResFuncGet()*.

*ifType*

Expects a media interface or network driver type from **m2Lib.h**

*protocol*

Expects a network service or protocol type from RFC 1700

*addrResFunc*

Expects a pointer to an address resolution function for this driver and protocol

**RETURNS** OK or ERROR.

**SEE ALSO** **muxLib**

---

## *muxAddrResFuncDel()*

**NAME** *muxAddrResFuncDel()* – delete an address resolution function

**SYNOPSIS**

```
STATUS muxAddrResFuncDel
(
 long ifType, /* ifType of function you want to delete */
 long protocol /* protocol from which to delete the function */
)
```

**DESCRIPTION** This function takes an *ifType* (from **m2Lib.h**) and a protocol (from RFC 1700) and deletes the associated address resolution routine (if such exists).

*ifType*

Expects a media interface or network driver type from **m2Lib.h**

*protocol*

Expects a network service or protocol type from RFC 1700

**RETURNS** OK or ERROR.

**SEE ALSO** **muxLib**

---

## ***muxAddrResFuncGet()***

**NAME** *muxAddrResFuncGet()* – get the address resolution function for *ifType*/protocol

**SYNOPSIS**

```
FUNCPTR muxAddrResFuncGet
(
 long ifType, /* ifType from m2Lib.h */
 long protocol /* protocol from RFC 1700 */
)
```

**DESCRIPTION** This routine takes an *ifType* (from **m2Lib.h**) and a protocol (from RFC 1700) and returns a pointer to the address resolution function registered for this *ifType*/protocol pair. If no such function exists then NULL is returned.

*ifType*

Expects a media interface or network driver type from **m2Lib.h**

*protocol*

Expects a network service or protocol type from RFC 1700

**RETURNS** FUNCPTR to the routine or NULL.

**SEE ALSO** **muxLib**

---

## *muxBind()*

**NAME** *muxBind()* – bind a protocol to the MUX given a driver name

**SYNOPSIS**

```
END_OBJ* muxBind
(
 char * pName, /* interface name, for example, ln, */
 int unit, /* unit number */
 BOOL (* stackRcvRtn) (void*
)
)
```

**DESCRIPTION** A protocol uses this routine to bind to a specific driver. The driver is specified by the *pName* and *unit* arguments (for example, ln and 0, ln and 1, ei and 0, ...). The *stackRcvRtn* is called whenever the MUX has a packet of the specified type. If the type is **MUX\_PROTO\_PROMISC**, the protocol is considered promiscuous and will get all of the packets that the MUX sees.

*pName*

Expects a pointer to a character string that contains the name of the device to which this protocol wants to use to send and receive packets.

*unit*

Expects a number which is the unit of the device of the type indicated by *pName*.

*stackRcvRtn*

Expects a pointer function that the MUX can call when it wants to pass a packet up to the protocol. For a description of how you should write this routine, see the description of a *stackRcvRtn()* provided in *Network Protocol Toolkit User's Guide*.

*stackShutdownRtn*

Expects a pointer to the function that the MUX can call to shutdown the protocol. For a description of how to write such a routine, see *stackShutdownRtn()* see the description of a *stackRcvRtn()* provided in *Network Protocol Toolkit User's Guide*.

*stackErrorRtn*

Expects a pointer to the function that the MUX can call to give errors to the protocol.

*type*

Expects a value that indicates the protocol type. The MUX uses this type to prioritize the protocol. For example, a protocol of type **MUX\_PROTO\_SNARF** has the highest priority (see the description of protocol prioritizing provided in *Network Protocol Toolkit User's Guide: Writing an NPT Protocol*. Aside from **MUX\_PROTO\_SNARF** and **MUX\_PROTO\_PROMISC**, valid protocol types include any of the values specified in RFC1700. If the type is **MUX\_PROTO\_OUTPUT**, this protocol is an output protocol and all packets that are going to be output on this device are passed to the *stackRcvRtn()* routine before actually being sent down to the device. This would be useful, for instance, for a network service that needs to send packets directly to

***muxDevExists()***

another network service, or for loop-back testing. If the *stackRcvRtn()* returns OK, the packet is considered to have been consumed and is no longer available. An output protocol may return ERROR from its *stackRcvRtn()* in order to look at the packet without consuming it.

*pProtoName*

Expects a pointer to a character string for the name of this protocol. This string can be NULL, in which case a protocol name is assigned internally.

*pSpare*

Expects a pointer to a structure defined by the protocol. This argument is passed up to the protocol with each received packet.

|                 |                                                                                  |
|-----------------|----------------------------------------------------------------------------------|
| <b>RETURNS</b>  | A cookie identifying the network driver to which the mux has bound the protocol. |
| <b>ERRNO</b>    | S_muxLib_NO_DEVICE, S_muxLib_ALREADY_BOUND, S_muxLib_ALLOC_FAILED                |
| <b>SEE ALSO</b> | <b>muxLib</b>                                                                    |

---

## ***muxDevExists()***

|                    |                                                                                                                                                                                                                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>muxDevExists()</i> – tests whether a device is already loaded into the MUX                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <pre> <b>BOOL</b> muxDevExists (     <b>char*</b> pName, /* string containing a device name (ln, ei, ...) */     <b>int</b>    unit  /* unit number */ ) </pre>                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>This routine takes a string device name (for example, ln or ei) and a unit number. If this device is already known to the MUX, it returns TRUE. | <b>DESCRIPTION</b> | <p>The <i>muxDevLoad()</i> routine loads a network driver into the MUX. Internally, this routine calls the specified <i>endLoad()</i> to initialize the software state of the device. After the device is initialized, <i>muxDevStart()</i> must be called to start the device.</p> <p><i>unit</i><br/>Expects the unit number of the device.</p> <p><i>endLoad</i><br/>Expects a pointer to the network driver's <i>endLoad()</i> entry point.</p> <p><i>pInitString</i><br/>Expects a pointer to an initialization string, a colon-delimited list of options. The <i>muxDevLoad()</i> routine passes this along blindly to the <i>endLoad()</i> function.</p> <p><i>loaning</i><br/>Expects a boolean value that tells the MUX whether the driver supports buffer loaning on this device. If the low-level device cannot support buffer loaning, passing in TRUE has no effect.</p> <p><i>pBSP</i><br/>This argument is passed blindly to the driver, which may or may not use it. It is provided so that the BSP can pass in tables of functions that the driver can use but which are specific to the particular BSP on which it runs.</p> |
| <b>RETURNS</b>     | A pointer to the new device or NULL if an error occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>NAME</b>        | <i>muxDevStart()</i> – start a device by calling its start routine                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <pre>STATUS muxDevStart (     void* pCookie /* a pointer to cookie returned by muxDevLoad() */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | <p>This routine starts a device that is already initialized and loaded into the MUX. Internally, <i>muxDevStart()</i> calls the device's <i>endStart()</i>, which handles registering the driver's interrupt service routine and whatever else is needed to allow the device to handle receiving and transmitting. This call to <i>endStart()</i> provides a device-dependent way to put the device into a running state.</p> <p><i>pCookie</i><br/>Expects a pointer to the <b>END_OBJ</b> returned from the <i>muxDevLoad()</i> that loaded this driver into the MUX. This "cookie" is an identifier for the device.</p> |
| <b>RETURNS</b>     | OK, ENETDOWN if <i>pCookie</i> does not represent a valid device, or ERROR if the start routine for the device fails.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>ERRNO</b>       | S_muxLib_NO_DEVICE                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SEE ALSO</b>    | <i>muxLib</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## ***muxDevStop()***

|                    |                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>muxDevStop()</i> – stop a device by calling its stop routine                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <pre>STATUS muxDevStop (     void* pCookie /* pointer to cookie that identifies the device */ )</pre>                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p>This routine stops the device specified in the <i>pCookie</i> parameter. Internally, <i>muxDevStop()</i> calls the device's own stop routine, thus putting the device into a stopped state in a device-dependent manner.</p> <p><i>pCookie</i><br/>Expects the pointer returned as the function value of the <i>muxDevLoad()</i> call for this</p> |

device. This pointer identifies the device to which the MUX has bound this protocol.

- RETURNS** OK, ENETDOWN if *pCookie* does not represent a valid device, or ERROR if the stop routine for the device fails.
- ERRNO** S\_muxLib\_NO\_DEVICE
- SEE ALSO** muxLib

## ***muxDevUnload()***

**NAME** *muxDevUnload()* – remove a driver from the MUX

**SYNOPSIS**

```
STATUS muxDevUnload
(
 char * pName, /* a string containing the name of the device */
 /* for example, ln or ei */
 int unit /* the unit number */
)
```

**DESCRIPTION** This routine unloads a driver from the MUX. This breaks any network connections an application might have open. The *stackShutdownRtn()* of each protocol bound to the END via *muxBind()* will be called. Each *stackShutdownRtn()* is expected to call *muxUnbind()* to detach from the END.

*pName*

Expects a pointer to a string containing the name of the device, for example **ln** or **ei**

*unit*

Expects the unit number of the device indicated by *pName*

**RETURNS** OK on success, EINVAL or ERROR if the device's registered *endUnload()* function failed, if the specified device was not found, or some other error occurred

**ERRNO** S\_muxLib\_UNLOAD\_FAILED, S\_muxLib\_NO\_DEVICE

**SEE ALSO** muxLib

---

## ***muxIoctl()***

**NAME** *muxIoctl()* – send control information to the MUX or to a device

**SYNOPSIS**

```
STATUS muxIoctl
(
 void* pCookie, /* cookie identifying the device to access */
 int cmd, /* command to pass to ioctl */
 caddr_t data /* data need for command in cmd */
)
```

**DESCRIPTION** This routine gives the protocol access to the network driver's control functions. The MUX itself can implement some of the standard control functions, so not all commands necessarily pass down to the device. Otherwise, both command and data pass down to the device unmolested.

This routine also lets the protocol change the routine that the MUX uses to pass data up to the protocol as well as the routine that the MUX uses to shutdown the protocol.

*pCookie*

Expects the pointer returned as the function value of *muxBind()*. The pointer identifies the device to which this protocol is bound.

*cmd*

Expects a value indicating the control command you want to execute. For valid *cmd* values, see the description of the *endIoctl()* routine provided in *Network Protocol Toolkit User's Guide*.

*data*

Expects the data or a pointer to the data needed to carry out the command specified in *cmd*.

**RETURNS** OK, ENETDOWN if *pCookie* does not represent a bound device, or ERROR if the command fails.

**ERRNO** S\_muxLib\_NO\_DEVICE

**SEE ALSO** *muxLib*

## ***muxMCastAddrDel()***

- NAME** *muxMCastAddrDel()* – delete a multicast address from a device’s multicast table
- SYNOPSIS**
- ```
STATUS muxMCastAddrDel
(
    void* pCookie, /* Returned by the muxBind() call */
    char* pAddress /* Address to delete from the table. */
)
```
- DESCRIPTION**
- This routine deletes an address from the multicast table maintained for a device. Internally, this function uses *pCookie* to find the device-specific routine that handles deleting an address from the device’s multicast table.
- pCookie*
- Expects the pointer returned as the function value of the *muxBind()* call. This pointer identifies the device to which the MUX bound this protocol.
- pAddress*
- Expects a pointer to a character string containing the address you want to delete.
- RETURNS** OK, ENETDOWN if *pCookie* does not represent a valid driver, or ERROR if the driver’s registered *endMCastAddrDel()* function fails.
- ERRNO** ENOTSUP, EINVAL, S_muxLib_NO_DEVICE
- SEE ALSO** **muxLib**

muxMCastAddrGet()

- NAME** *muxMCastAddrGet()* – get the multicast address table from the MUX/Driver
- SYNOPSIS**
- ```
int muxMCastAddrGet
(
 void* pCookie, /* returned by the muxBind() call */
 MULTI_TABLE * pTable /* ptr to a table to be filled and returned. */
)
```
- DESCRIPTION**
- This routine expects a buffer into which it can write the list of multicast addresses for the specified device. Internally, this routine uses *pCookie* to access the device-specific routine needed to retrieve the multicast address table.

*pCookie*

Expects the pointer returned as the function value of the *muxBind()* call. This pointer identifies the device to which the MUX has bound this protocol.

*pTable*

Expects the pointer to a **MULTI\_TABLE** structure. You must have allocated this structure at some time before the call to *muxMCastAddrGet()*. The **MULTI\_TABLE** structure is defined in **end.h** as:

```
typedef struct multi_table
{
 int tableLen; /* length of table in bytes */
 char *pTable; /* pointer to entries */
} MULTI_TABLE;
```

**RETURNS** OK, ENETDOWN if *pCookie* does not represent a valid driver, or ERROR if the driver's registered *endMCastAddrGet()* function fails.

**ERRNO** S\_muxLib\_NO\_DEVICE

**SEE ALSO** muxLib

## *muxPacketAddrGet()*

**NAME** *muxPacketAddrGet()* – get addressing information from a packet

**SYNOPSIS** STATUS *muxPacketAddrGet*

```
(
 void* pCookie, /* cookie that identifies the device */
 M_BLK_ID pMblk, /* structure to contain packet */
 M_BLK_ID pSrcAddr, /* structure containing source address */
 M_BLK_ID pDstAddr, /* structure containing destination address */
 M_BLK_ID pESrcAddr, /* structure containing the end source */
 M_BLK_ID pEDstAddr /* structure containing the end destination */
)
```

**DESCRIPTION** This routine takes a pointer to cookie that was handed back by *muxBind()*, an **M\_BLK\_ID** that came from a device and up to four **M\_BLK\_ID**'s that can receive data pointers.

The routine returns appropriate information on the immediate source, immediate destination, ultimate source and, ultimate destination addresses from the packet pointed to in the first **M\_BLK\_ID**. This routine is a pass through to the device's own routine which knows how to interpret packets that it has received.

*pCookie*

Expects the cookie returned from the *muxBind()* call. This cookie identifies the device to which the MUX bound this protocol.

*pMblk*

Expects an **M\_BLK\_ID** representing packet data from which the addressing information is to be extracted

*pSrcAddr*

Expects NULL or an **M\_BLK\_ID** which will hold the local source address extracted from the packet

*pDstAddr*

Expects NULL or an **M\_BLK\_ID** which will hold the local destination address extracted from the packet

*pESrcAddr*

Expects NULL or an **M\_BLK\_ID** which will hold the end source address extracted from the packet

*pEDstAddr*

Expects NULL or an **M\_BLK\_ID** which will hold the end destination address extracted from the packet

**RETURNS** OK or ERROR.

**ERRNO** S\_muxLib\_NO\_DEVICE

**SEE ALSO** muxLib

---

## ***muxPacketDataGet()***

**NAME** *muxPacketDataGet()* – return the data from a packet

**SYNOPSIS**

```
STATUS muxPacketDataGet
(
 void* pCookie, /* cookie that identifies the device */
 M_BLK_ID pMblk, /* returns the packet data */
 LL_HDR_INFO * pLinkHdrInfo /* the new data is returned here */
)
```

**DESCRIPTION** This routine copies the header information from the packet referenced in *pMblk* into the **LL\_HDR\_INFO** structure referenced in *pLinkHdrInfo*.

*pCookie*

Expects the cookie returned from the *muxBind()* call. This cookie identifies the device to which the MUX bound this protocol.

*pMblk*

Expects a pointer to an **mBlk** or **mBlk** cluster representing a packet containing the data to be returned

*pLinkHdrInfo*

Expects a pointer to an **LL\_HDR\_INFO** structure into which the packet header information is copied from the incoming **mBlk**

**RETURNS** OK or ERROR if the device type is not recognized.

**ERRNO** S\_muxLib\_NO\_DEVICE

**SEE ALSO** muxLib

---

## ***muxPollReceive()***

**NAME** *muxPollReceive()* – poll for a packet from a device driver

**SYNOPSIS**

```
STATUS muxPollReceive
(
 void* pCookie, /* cookie passed in endLoad call */
 M_BLK_ID pNBuf /* a vector of buffers passed to us */
)
```

**DESCRIPTION** This is the routine that an upper layer can call to poll for a packet.

*pCookie*

Expects the cookie that was returned from *muxBind()*. This "cookie" is an identifier for the driver.

*pNBuf*

Expects a pointer to a buffer chain into which incoming data will be put.

**RETURNS** OK, ENETDOWN if *pCookie* does not represent a loaded driver, or an error value returned from the driver's registered *endPollReceive()* function.

**ERRNO** S\_muxLib\_NO\_DEVICE

**SEE ALSO** muxLib

## ***muxPollSend()***

**NAME** *muxPollSend()* – send a packet on a network interface

**SYNOPSIS**

```
STATUS muxPollSend
(
 void* pCookie, /* cookie the protocol got from muxBind() */
 M_BLK_ID pNBuf /* data to be sent */
)
```

**DESCRIPTION** This routine takes a cookie which was returned by *muxBind()* and uses it to determine which network interface driver should be used in transmitting the data. The routine takes the data pointed to by *pNBuf* and sends it to the destination specified by calling the functions in that driver.

*pCookie*

Expects the cookie returned from *muxBind()*. This Cookie identifies the device to which the MUX has bound the protocol calling *muxPollSend()*.

*pNBuf*

Expects a pointer to the buffer(**mBlk**) chain that contains the packet to be transmitted.

**RETURNS** OK, ENETDOWN if *pCookie* doesn't represent a valid device, or ERROR if the device type is not recognized or if the *endPollSend()* routine for the driver fails.

**ERRNO** S\_muxLib\_NO\_DEVICE

**SEE ALSO** *muxLib*

---

## ***muxSend()***

**NAME** *muxSend()* – send a packet out on a network interface

**SYNOPSIS**

```
STATUS muxSend
(
 void* pCookie, /* cookie that identifies a network interface */
 /* by muxBind() */
 M_BLK_ID pNBuf /* data to be sent */
)
```

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | <p>This routine uses the <i>pCookie</i> value returned during the bind to identify the network interface through which the packet is to be transmitted.</p> <p><i>pCookie</i><br/>         Expects the pointer returned from <i>muxBind()</i>. This pointer identifies the device to which the MUX has bound this protocol.</p> <p><i>pNBuf</i><br/>         Expects a pointer to the buffer that contains the packet you want to transmit. Before you call <i>muxSend()</i>, you need to put the addressing information at the head of the buffer. To do this, call <i>muxAddressForm()</i>.</p> <p>Also, the buffer should probably be reserved from the MUX- managed memory pool. To reserve a buffer from this pool, the protocol should call <i>muxBufAlloc()</i>.</p> |
| <b>RETURNS</b>     | OK, ENETDOWN if <i>pCookie</i> does not represent a valid interface, or ERROR if the driver's <i>endSend()</i> routine fails.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>ERRNO</b>       | S_muxLib_NO_DEVICE                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SEE ALSO</b>    | <b>muxLib</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>DESCRIPTION</b> | <p>If a driver is specified <i>pDevName</i> and <i>unit</i>, this routine reports the name and type of each protocol bound to it. If a <i>pDevName</i> is not given, the entire list of devices and their protocols is shown.</p> <p><i>pDevName</i><br/>         Expects a pointer to a string containing the device name, or NULL</p> <p><i>unit</i><br/>         Expects a unit number for the device</p> |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                                                                                                                                                          |

|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <b><i>muxUnbind()</i></b> – detach a protocol from the specified driver                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <pre>STATUS muxUnbind (     void*   pCookie,    /* pointer to identifier for device */     long    type,       /* device type passed in muxBind() call */     FUNCPTR stackRcvRtn /* pointer to stack receive routine */ )</pre>                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>This routine disconnects a protocol from the specified driver.</p> <p><i>pCookie</i><br/>Expects the pointer returned as the function value from the <b><i>muxBind()</i></b> call. This pointer identifies the device to which the MUX has bound this protocol.</p> <p><i>type</i><br/>This is the type that you passed down in the <b><i>muxBind()</i></b> call.</p> <p><i>stackRcvRtn</i><br/>Expects a pointer to the stack receive routine you specified when you called <b><i>muxBind()</i></b> to bind the driver and protocol.</p> |
| <b>RETURNS</b>     | OK, EINVAL if <i>pCookie</i> does not represent a valid driver or the protocol is not attached, ERROR if <b><i>muxUnbind()</i></b> fails.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>ERRNO</b>       | EINVAL, S_muxLib_NO_DEVICE                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                 |                                                                                                                                                           |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>     | <b><i>nanosleep()</i></b> – suspend the current task until the time interval elapses (POSIX)                                                              |
| <b>SYNOPSIS</b> | <pre>int nanosleep (     const struct timespec * rqt, /* time to delay */     struct timespec *      rmt, /* premature wakeup (NULL=no result) */ )</pre> |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | <p>This routine suspends the current task for a specified time <i>rqtpor</i> until a signal or event notification is made.</p> <p>The suspension may be longer than requested due to the rounding up of the request to the timer's resolution or to other scheduling activities (e.g., a higher priority task intervenes).</p> <p>If <i>rmtp</i> is non-NULL, the <b>timespec</b> structure is updated to contain the amount of time remaining. If <i>rmtp</i> is NULL, the remaining time is not returned. The <i>rqtp</i> parameter is greater than 0 or less than or equal to 1,000,000,000.</p> |
| <b>RETURNS</b>     | 0 (OK), or -1 (ERROR) if the routine is interrupted by a signal or an asynchronous event notification, or <i>rqtp</i> is invalid.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>ERRNO</b>       | EINVAL, EINTR                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>NAME</b>        | <b><i>ncr710CtrlCreate()</i></b> – create a control structure for an NCR 53C710 SIOP                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <pre> NCR_710_SCSI_CTRL *ncr710CtrlCreate (     UINT8 * baseAdrs, /* base address of the SIOP */     UINT   freqValue /* clock controller period (nsec* 100) */ ) </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>This routine creates an SIOP data structure and must be called before using an SIOP chip. It should be called once and only once for a specified SIOP. Since it allocates memory for a structure needed by all routines in <b>ncr710Lib</b>, it must be called before any other routines in the library. After calling this routine, <b><i>ncr710CtrlInit()</i></b> should be called at least once before any SCSI transactions are initiated using the SIOP.</p> <p>A detailed description of the input parameters follows:</p> <p><i>baseAdrs</i><br/>the address at which the CPU accesses the lowest register of the SIOP.</p> <p><i>freqValue</i><br/>the value at the SIOP SCSI clock input. This is used to determine the clock period for the SCSI core of the chip and the synchronous divider value for synchronous transfer. It is important to have the right timing on the SCSI bus. The <i>freqValue</i> parameter is defined as the SCSI clock input value, in nanoseconds, multiplied by 100. Several <i>freqValue</i> constants are defined in <b>ncr710.h</b> as follows:</p> |

```
NCR710_1667MHZ 5998 /* 16.67Mhz chip */
NCR710_20MHZ 5000 /* 20Mhz chip */
NCR710_25MHZ 4000 /* 25Mhz chip */
NCR710_3750MHZ 2666 /* 37.50Mhz chip */
NCR710_40MHZ 2500 /* 40Mhz chip */
NCR710_50MHZ 2000 /* 50Mhz chip */
NCR710_66MHZ 1515 /* 66Mhz chip */
NCR710_6666MHZ 1500 /* 66.66Mhz chip */
```

**RETURNS** A pointer to the `NCR_710_SCSI_CTRL` structure, or `NULL` if memory is insufficient or parameters are invalid.

**SEE ALSO** `ncr710Lib`

---

## ***ncr710CtrlCreateScsi2()***

**NAME** `ncr710CtrlCreateScsi2()` – create a control structure for the NCR 53C710 SIOP

**SYNOPSIS**

```
NCR_710_SCSI_CTRL *ncr710CtrlCreateScsi2
(
 UINT8 * baseAdrs, /* base address of the SIOP */
 UINT clkPeriod /* clock controller period (nsec* 100) */
)
```

**DESCRIPTION** This routine creates an SIOP data structure and must be called before using an SIOP chip. It must be called exactly once for a specified SIOP controller. Since it allocates memory for a structure needed by all routines in `ncr710Lib`, it must be called before any other routines in the library. After calling this routine, `ncr710CtrlInitScsi2()` must be called at least once before any SCSI transactions are initiated using the SIOP.

A detailed description of the input parameters follows:

*baseAdrs*

the address at which the CPU accesses the lowest (SCNTL0/SIEN) register of the SIOP.

*clkPeriod*

the period of the SIOP SCSI clock input, in nanoseconds, multiplied by 100. This is used to determine the clock period for the SCSI core of the chip and affects the timing of both asynchronous and synchronous transfers. Several commonly used values are defined in `ncr710.h` as follows:

```
NCR710_1667MHZ 6000 /* 16.67Mhz chip */
NCR710_20MHZ 5000 /* 20Mhz chip */
```

```

NCR710_25MHZ 4000 /* 25Mhz chip */
NCR710_3750MHZ 2667 /* 37.50Mhz chip */
NCR710_40MHZ 2500 /* 40Mhz chip */
NCR710_50MHZ 2000 /* 50Mhz chip */
NCR710_66MHZ 1515 /* 66Mhz chip */
NCR710_6666MHZ 1500 /* 66.66Mhz chip */

```

**RETURNS** A pointer to the `NCR_710_SCSI_CTRL` structure, or `NULL` if memory is unavailable or there are invalid parameters.

**SEE ALSO** `ncr710Lib2`

---

## *ncr710CtrlInit()*

**NAME** *ncr710CtrlInit()* – initialize a control structure for an NCR 53C710 SIOP

**SYNOPSIS**

```

STATUS ncr710CtrlInit
(
 NCR_710_SCSI_CTRL * pSiop, /* ptr to SIOP struct */
 int scsiCtrlBusId, /* SCSI bus ID of this SIOP */
 int scsiPriority /* priority of task when doing SCSI */
)

```

**DESCRIPTION** This routine initializes an SIOP structure, after the structure is created with *ncr710CtrlCreate()*. This structure must be initialized before the SIOP can be used. It may be called more than once; however, it should be called only while there is no activity on the SCSI interface.

Before returning, this routine pulses RST (reset) on the SCSI bus, thus resetting all attached devices.

The input parameters are as follows:

*pSiop*

a pointer to the `NCR_710_SCSI_CTRL` structure created with *ncr710CtrlCreate()*.

*scsiCtrlBusId*

the SCSI bus ID of the SIOP, in the range 0 – 7. The ID is somewhat arbitrary; the value 7, or highest priority, is conventional.

*scsiPriority*

the priority to which a task is set when performing a SCSI transaction. Valid priorities are 0 to 255. Alternatively, the value -1 specifies that the priority should not be altered during SCSI transactions.

**RETURNS** OK, or ERROR if parameters are out of range.

**SEE ALSO** ***ncr710Lib***

---

## ***ncr710CtrlInitScsi2()***

**NAME** ***ncr710CtrlInitScsi2()*** – initialize a control structure for the NCR 53C710 SIOP

**SYNOPSIS**

```
STATUS ncr710CtrlInitScsi2
(
 NCR_710_SCSI_CTRL * pSiop, /* ptr to SIOP struct */
 int scsiCtrlBusId, /* SCSI bus ID of this SIOP */
 int scsiPriority /* task priority when doing SCSI I/O */
)
```

**DESCRIPTION** This routine initializes an SIOP structure after the structure is created with ***ncr710CtrlCreateScsi2()***. This structure must be initialized before the SIOP can be used. It may be called more than once if needed; however, it must only be called while there is no activity on the SCSI interface.

A detailed description of the input parameters follows:

*pSiop*

a pointer to the NCR\_710\_SCSI\_CTRL structure created with ***ncr710CtrlCreateScsi2()***.

*scsiCtrlBusId*

the SCSI bus ID of the SIOP. Its value is somewhat arbitrary: seven (7), or highest priority, is conventional. The value must be in the range 0 – 7.

*scsiPriority*

this parameter is ignored. All SCSI I/O is now done in the context of the SCSI manager task; if necessary, the priority of the manager task may be changed using ***taskPrioritySet()*** or by setting the value of the global variable ***ncr710ScsiTaskPriority*** before calling ***ncr710CtrlCreateScsi2()***.

**RETURNS** OK, or ERROR if the parameters are out of range.

**SEE ALSO** ***ncr710Lib2***, ***ncr710CtrlCreateScsi2()***

---

## *ncr710SetHwRegister()*

**NAME** *ncr710SetHwRegister()* – set hardware-dependent registers for the NCR 53C710 SIOP

**SYNOPSIS**

```
STATUS ncr710SetHwRegister
(
 SIOP * pSiop, /* pointer to SIOP info */
 NCR710_HW_REGS * pHwRegs /* pointer to NCR710_HW_REGS info */
)
```

**DESCRIPTION** This routine sets up the registers used in the hardware implementation of the chip. Typically, this routine is called by the *sysScsiInit()* routine from the board support package.

The input parameters are as follows:

*pSiop*

a pointer to the `NCR_710_SCSI_CTRL` structure created with *ncr710CtrlCreate()*.

*pHwRegs*

a pointer to a `NCR710_HW_REGS` structure that is filled with the logical values 0 or 1 for each bit of each register described below.

This routine includes only the bit registers that can be used to modify the behavior of the chip. The default configuration used during *ncr710CtrlCreate()* and *ncr710CtrlInit()* is {0,0,0,0,1,0,0,0,0,0,0,0,0,1,0}.

```
typedef struct
{
 int ctest4Bit7; /* host bus multiplex mode */
 int ctest7Bit7; /* disable/enable burst cache capability */
 int ctest7Bit6; /* snoop control bit1 */
 int ctest7Bit5; /* snoop control bit0 */
 int ctest7Bit1; /* invert ttl pin (sync bus host mode only) */
 int ctest7Bit0; /* enable differential SCSI bus capability */
 int ctest8Bit0; /* set snoop pins mode */
 int dmodeBit7; /* burst length transfer bit 1 */
 int dmodeBit6; /* burst length transfer bit 0 */
 int dmodeBit5; /* function code bit FC2 */
 int dmodeBit4; /* function code bit FC1 */
 int dmodeBit3; /* program data bit (FC0) */
 int dmodeBit1; /* user-programmable transfer type */
 int dcntlBit5; /* enable ACK pin */
 int dcntlBit1; /* enable fast arbitration on host port */
} NCR710_HW_REGS;
```

For a more detailed description of the register bits, see the *NCR 53C710 SCSI I/O Processor Programming Guide*.

- NOTE** Because this routine writes to the NCR 53C710 chip registers, it cannot be used when there is any SCSI bus activity.
- RETURNS** OK, or ERROR if an input parameter is NULL.
- SEE ALSO** *ncr710Lib*, *ncr710CtrlCreate()*, *NCR 53C710 SCSI I/O Processor Programming Guide*

---

## ***ncr710SetHwRegisterScsi2()***

**NAME** *ncr710SetHwRegisterScsi2()* – set hardware-dependent registers for the NCR 53C710

**SYNOPSIS**

```
STATUS ncr710SetHwRegisterScsi2
(
 SIOP * pSiop, /* pointer to SIOP info */
 NCR710_HW_REGS * pHwRegs /* pointer to a NCR710_HW_REGS info */
)
```

**DESCRIPTION** This routine sets up the registers used in the hardware implementation of the chip. Typically, this routine is called by the *sysScsiInit()* routine from the BSP.

The input parameters are as follows:

*pSiop*  
a pointer to the *NCR\_710 SCSI\_CTRL* structure created with *ncr710CtrlCreateScsi2()*.

*pHwRegs*  
a pointer to a *NCR710\_HW\_REGS* structure that is filled with the logical values 0 or 1 for each bit of each register described below.

This routine includes only the bit registers that can be used to modify the behavior of the chip. The default configuration used during *ncr710CtrlCreateScsi2()* and *ncr710CtrlInitScsi2()* is {0,0,0,0,1,0,0,0,0,0,0,0,0,1,0}.

```
typedef struct
{
 int ctest4Bit7; /* Host bus multiplex mode */
 int ctest7Bit7; /* Disable/enable burst cache capability */
 int ctest7Bit6; /* Snoop control bit1 */
 int ctest7Bit5; /* Snoop control bit0 */
 int ctest7Bit1; /* invert ttl pin (sync bus host mode only)*/
 int ctest7Bit0; /* enable differential scsi bus capability*/
 int ctest8Bit0; /* Set snoop pins mode */
}
```

```

int dmodeBit7; /* Burst Length transfer bit 1 */
int dmodeBit6; /* Burst Length transfer bit 0 */
int dmodeBit5; /* Function code bit FC2 */
int dmodeBit4; /* Function code bit FC1 */
int dmodeBit3; /* Program data bit (FC0) */
int dmodeBit1; /* user programmable transfer type */
int dcntlBit5; /* Enable Ack pin */
int dcntlBit1; /* Enable fast arbitration on host port */
} NCR710_HW_REGS;

```

For a more detailed explanation of the register bits, refer to the *NCR 53C710 SCSI I/O Processor Programming Guide*.

- NOTE** Because this routine writes to the chip registers you cannot use it if there is any SCSI bus activity.
- RETURNS** OK, or ERROR if any input parameter is NULL.
- SEE ALSO** *ncr710Lib2*, *ncr710CtrlCreateScsi2()*, *NCR 53C710 SCSI I/O Processor Programming Guide*

## ***ncr710Show()***

- NAME** *ncr710Show()* – display the values of all readable NCR 53C710 SIOP registers
- SYNOPSIS**
- ```

STATUS ncr710Show
(
    SCSI_CTRL * pScsiCtrl /* ptr to SCSI controller info */
)

```
- DESCRIPTION** This routine displays the state of the NCR 53C710 SIOP registers in a user-friendly manner. It is useful primarily for debugging. The input parameter is the pointer to the SIOP information structure returned by the *ncr710CtrlCreate()* call.
- NOTE** The only readable register during a script execution is the Istat register. If this routine is used during the execution of a SCSI command, the result could be unpredictable.

EXAMPLE

```

-> ncr710Show
NCR710 Registers
-----
0xffff47000: Sien      = 0xa5 Sdid      = 0x00 Scntl1   = 0x00 Scntl0   = 0x04
0xffff47004: Socl      = 0x00 Sodl      = 0x00 Sxfer    = 0x80 Scid      = 0x80
0xffff47008: Sbcl      = 0x00 Sbd1      = 0x00 Sid1     = 0x00 Sfbr     = 0x00
0xffff4700c: Sstat2     = 0x00 Sstat1    = 0x00 Sstat0   = 0x00 Dstat     = 0x80

```

```
0xffff47010: Dsa      = 0x00000000
0xffff47014: Ctest3   = ????. Ctest2   = 0x21 Ctest1   = 0xf0 Ctest0   = 0x00
0xffff47018: Ctest7   = 0x32 Ctest6   = ????. Ctest5   = 0x00 Ctest4   = 0x00
0xffff4701c: Temp     = 0x00000000
0xffff47020: Lcrc    = 0x00 Ctest8   = 0x00 Istat    = 0x00 Dfifo    = 0x00

0xffff47028: Dnad    = 0x00066144
0xffff4702c: Dsp     = 0x00066144
0xffff47030: Dsps    = 0x00066174
0xffff47037: Scratch3= 0x00 Scratch2= 0x00 Scratch1= 0x00 Scratch0= 0x0a
0xffff47038: Dcntl   = 0x21 Dwt     = 0x00 Dien    = 0x37 Dmode    = 0x01
0xffff4703c: Adder   = 0x00cc2b8
```

RETURNS OK, or ERROR if *pScsiCtrl* and *pSysScsiCtrl* are both NULL.

SEE ALSO *ncr710Lib*, *ncr710CtrlCreate()*

ncr710ShowScsi2()

NAME *ncr710ShowScsi2()* – display the values of all readable NCR 53C710 SIOP registers

SYNOPSIS

```
STATUS ncr710ShowScsi2
(
    SCSI_CTRL * pScsiCtrl /* ptr to SCSI controller info */
)
```

DESCRIPTION This routine displays the state of the NCR 53C710 SIOP registers in a user-friendly way. It is primarily used for debugging. The input parameter is the pointer to the SIOP information structure returned by the *ncr710CtrlCreateScsi2()* call.

NOTE The only readable register during a script execution is the Istat register. If you use this routine during the execution of a SCSI command, the result could be unpredictable.

EXAMPLE

```
-> ncr710Show

RETURNS OK, or ERROR if *pScsiCtrl* and *pSysScsiCtrl* are both NULL.

SEE ALSO *ncr710Lib2*, *ncr710CtrlCreateScsi2()*

ncr810CtrlCreate()

NAME *ncr810CtrlCreate()* – create a control structure for the NCR 53C8xx SIOP

SYNOPSIS

```

NCR_810_SCSI_CTRL *ncr810CtrlCreate
(
    UINT8 * baseAdrs, /* base address of the SIOP */
    UINT   clkPeriod, /* clock controller period (nsec* 100) */
    UINT16 devType    /* NCR8XX SCSI device type */
)

```

DESCRIPTION This routine creates an SIOP data structure and must be called before using an SIOP chip. It must be called exactly once for a specified SIOP controller. Since it allocates memory for a structure needed by all routines in **ncr810Lib**, it must be called before any other routines in the library. After calling this routine, *ncr810CtrlInit()* must be called at least once before any SCSI transactions are initiated using the SIOP.

A detailed description of the input parameters follows:

baseAdrs
the address at which the CPU accesses the lowest (SCNTL0/SIEN) register of the SIOP.

clkPeriod
the period of the SIOP SCSI clock input, in nanoseconds, multiplied by 100. This is used to determine the clock period for the SCSI core of the chip and affects the timing of both asynchronous and synchronous transfers. Several commonly-used values are defined in **ncr810.h** as follows:

ncr810CtrlInit()

```

NCR810_1667MHZ  6000  /* 16.67Mhz chip */
NCR810_20MHZ    5000  /* 20Mhz chip   */
NCR810_25MHZ    4000  /* 25Mhz chip   */
NCR810_3750MHZ  2667  /* 37.50Mhz chip */
NCR810_40MHZ    2500  /* 40Mhz chip   */
NCR810_50MHZ    2000  /* 50Mhz chip   */
NCR810_66MHZ    1515  /* 66Mhz chip   */
NCR810_6666MHZ  1500  /* 66.66Mhz chip */

```

devType

the specific NCR 8xx device type. Current device types are defined in the header file `ncr810.h`.

RETURNS A pointer to the `NCR_810_SCSI_CTRL` structure, or NULL if memory is unavailable or there are invalid parameters.

SEE ALSO `ncr810Lib`

ncr810CtrlInit()

NAME `ncr810CtrlInit()` – initialize a control structure for the NCR 53C8xx SIOP

SYNOPSIS `STATUS ncr810CtrlInit`

```

(
  NCR_810_SCSI_CTRL * pSiop,          /* ptr to SIOP struct */
  int                scsiCtrlBusId /* SCSI bus ID of this SIOP */
)

```

DESCRIPTION This routine initializes an SIOP structure, after the structure is created with `ncr810CtrlCreate()`. This structure must be initialized before the SIOP can be used. It may be called more than once if needed; however, it must only be called while there is no activity on the SCSI interface. A detailed description of the input parameters follows:

pSiop

a pointer to the `NCR_810_SCSI_CTRL` structure created with `ncr810CtrlCreate()`.

scsiCtrlBusId

the SCSI bus ID of the SIOP. Its value is somewhat arbitrary: seven (7), or highest priority, is conventional. The value must be in the range 0 – 7.

RETURNS OK, or ERROR if parameters are out of range.

SEE ALSO `ncr810Lib`

ncr810SetHwRegister()

NAME *ncr810SetHwRegister()* – set hardware-dependent registers for the NCR 53C8xx SIOP

SYNOPSIS

```
STATUS ncr810SetHwRegister
(
    SIOP *          pSiop, /* pointer to SIOP info */
    NCR810_HW_REGS * pHwRegs /* pointer to a NCR810_HW_REGS info */
)
```

DESCRIPTION This routine sets up the registers used in the hardware implementation of the chip. Typically, this routine is called by the *sysScsiInit()* routine from the BSP.

The input parameters are as follows:

pSiop

a pointer to the NCR_810 SCSI_CTRL structure created with *ncr810CtrlCreate()*.

pHwRegs

a pointer to a NCR810_HW_REGS structure that is filled with the logical values 0 or 1 for each bit of each register described below.

This routine includes only the bit registers that can be used to modify the behavior of the chip. The default configuration used during *ncr810CtrlCreate()* and *ncr810CtrlInit()* is {0,0,0,0,0,1,0,0,0,0,0}.

```
typedef struct
{
    int stest1Bit7;          /* Disable external SCSI clock */
    int stest2Bit7;          /* SCSI control enable */
    int stest2Bit5;          /* Enable differential SCSI bus */
    int stest2Bit2;          /* Always WIDE SCSI */
    int stest2Bit1;          /* Extend SREQ/SACK filtering */
    int stest3Bit7;          /* TolerANT enable */
    int dmodeBit7;           /* Burst Length transfer bit 1 */
    int dmodeBit6;           /* Burst Length transfer bit 0 */
    int dmodeBit5;           /* Source I/O memory enable */
    int dmodeBit4;           /* Destination I/O memory enable */
    int scntl1Bit7;          /* Slow cable mode */
} NCR810_HW_REGS;
```

For a more detail on the register bits, see the appropriate NCR 53C8xx data manuals.

NOTE Because this routine writes to the NCR 53C8xx chip registers, it cannot be used when there is any SCSI bus activity.

RETURNS OK, or ERROR if any input parameter is NULL

SEE ALSO [ncr810Lib](#), [ncr810.h](#), [ncr810CtrlCreate\(\)](#)

ncr810Show()

NAME *ncr810Show()* – display values of all readable NCR 53C8xx SIOP registers

SYNOPSIS

```
STATUS ncr810Show
(
    SCSI_CTRL * pScsiCtrl /* ptr to SCSI controller info */
)
```

DESCRIPTION This routine displays the state of the SIOP registers in a user-friendly way. It is useful primarily for debugging. The input parameter is the pointer to the SIOP information structure returned by the *ncr810CtrlCreate()* call.

NOTE The only readable register during a script execution is the Istat register. If you use this routine during the execution of a SCSI command, the result could be unpredictable.

EXAMPLE

```
-> ncr810Show
NCR810 Registers
-----
0xffff47000: Sien   = 0xa5 Sdid   = 0x00 Scnt11  = 0x00 Scnt10  = 0x04
0xffff47004: Socl   = 0x00 Sodl   = 0x00 Sxfer   = 0x80 Scid   = 0x80
0xffff47008: Sbcl   = 0x00 Sbdl   = 0x00 Sidl   = 0x00 Sfbr   = 0x00
0xffff4700c: Sstat2 = 0x00 Sstat1 = 0x00 Sstat0 = 0x00 Dstat   = 0x80
0xffff47010: Dsa    = 0x00000000
0xffff47014: Ctest3 = ??? Ctest2 = 0x21 Ctest1 = 0xf0 Ctest0 = 0x00
0xffff47018: Ctest7 = 0x32 Ctest6 = ??? Ctest5 = 0x00 Ctest4 = 0x00
0xffff4701c: Temp   = 0x00000000
0xffff47020: Lcrc   = 0x00 Ctest8 = 0x00 Istat   = 0x00 Dfifo   = 0x00
0xffff47024: Dcmd/Ddc= 0x50000000
0xffff47028: Dnad   = 0x00066144
0xffff4702c: Dsp    = 0x00066144
0xffff47030: Dsps   = 0x00066174
0xffff47037: Scratch3= 0x00 Scratch2= 0x00 Scratch1= 0x00 Scratch0= 0x0a
0xffff47038: Dcnt1  = 0x21 Dwt    = 0x00 Dien   = 0x37 Dmode   = 0x01
0xffff4703c: Adder  = 0x000cc2b8
value = 0 = 0x0
```

RETURNS OK, or ERROR if *pScsiCtrl* and *pSysScsiCtrl* are both NULL.

SEE ALSO [ncr810Lib](#), [ncr810CtrlCreate\(\)](#)

ncr5390CtrlCreate()

NAME *ncr5390CtrlCreate()* – create a control structure for an NCR 53C90 ASC

SYNOPSIS

```
NCR_5390_SCSI_CTRL *ncr5390CtrlCreate
(
    UINT8 * baseAdrs,      /* base address of ASC */
    int    regOffset,     /* addr offset between consecutive regs. */
    UINT   clkPeriod,     /* period of controller clock (nsec) */
    FUNCPTR ascDmaBytesIn, /* SCSI DMA input function */
    FUNCPTR ascDmaBytesOut /* SCSI DMA output function */
)
```

DESCRIPTION This routine creates a data structure that must exist before the ASC chip can be used. This routine must be called exactly once for a specified ASC, and must be the first routine called, since it `calloc`'s a structure needed by all other routines in the library.

The input parameters are as follows:

baseAdrs

the address at which the CPU would access the lowest register of the ASC.

regOffset

the address offset (bytes) to access consecutive registers. (This must be a power of 2, for example, 1, 2, 4, etc.)

clkPeriod

the period, in nanoseconds, of the signal to the ASC clock input (used only for select command timeouts).

ascDmaBytesIn and *ascDmaBytesOut*

board-specific parameters to handle DMA input and output. If these are NULL (0), ASC program transfer mode is used. DMA is possible only during SCSI data in/out phases. The interface to these DMA routines must be of the form:

```
STATUS xxDmaBytes{In, Out}
(
    SCSI_PHYS_DEV *pScsiPhysDev, /* ptr to phys dev info */
    UINT8         *pBuffer,      /* ptr to the data buffer */
    int           bufLength      /* number of bytes to xfer */
)
```

RETURNS A pointer to an `NCR_5390_SCSI_CTRL` structure, or NULL if memory is insufficient or the parameters are invalid.

SEE ALSO `ncr5390Lib1`

ncr5390CtrlCreateScsi2()

NAME *ncr5390CtrlCreateScsi2()* – create a control structure for an NCR 53C90 ASC

SYNOPSIS

```
NCR_5390_SCSI_CTRL *ncr5390CtrlCreateScsi2
(
    UINT8* baseAdrs,           /* base address of ASC */
    int    regOffset,         /* offset between consecutive regs. */
    UINT   clkPeriod,        /* period of controller clock (nsec) */
    UINT   sysScsiDmaMaxBytes, /* maximum byte count using DMA */
    FUNCPTR sysScsiDmaStart,  /* function to start SCSI DMA xfer */
    FUNCPTR sysScsiDmaAbort,  /* function to abort SCSI DMA xfer */
    int    sysScsiDmaArg     /* argument to pass to above funcs. */
)
```

DESCRIPTION This routine creates a data structure that must exist before the ASC chip can be used. This routine must be called exactly once for a specified ASC, and must be the first routine called, since it `calloc`'s a structure needed by all other routines in the library.

The input parameters are as follows:

baseAdrs

the address at which the CPU would access the lowest register of the ASC.

regOffset

the address offset (bytes) to access consecutive registers.

clkPeriod

the period, in nanoseconds, of the signal to the ASC clock input.

sysScsiDmaMaxBytes, *sysScsiDmaStart*, *sysScsiDmaAbort*, and *sysScsiDmaArg*

board-specific routines to handle DMA transfers to and from the ASC; if the maximum DMA byte count is zero, programmed I/O is used. Otherwise, non-NULL function pointers to DMA start and abort routines must be provided. The specified argument is passed to these routines when they are called; it may be used to identify the DMA channel to use, for example. The interface to these DMA routines must be of the form:

```
STATUS xxDmaStart (arg, pBuffer, bufLength, direction)
    int arg;           /* call-back argument */
    UINT8 *pBuffer;   /* ptr to the data buffer */
    UINT bufLength;   /* number of bytes to xfer */
    int direction;    /* 0 = SCSI->mem, 1 = mem->SCSI */
STATUS xxDmaAbort (arg)
    int arg;          /* call-back argument */
```

Implementation details for the DMA routines can be found in the specific DMA driver for that board.

- NOTE** If there is no DMA interface, synchronous transfers are not supported. This is a limitation of the NCR5390 hardware.
- RETURNS** A pointer to an `NCR_5390_SCSI_CTRL` structure, or `NULL` if memory is insufficient or the parameters are invalid.
- SEE ALSO** `ncr5390Lib2`

ncr5390CtrlInit()

NAME *ncr5390CtrlInit()* – initialize the user-specified fields in an ASC structure

SYNOPSIS

```
STATUS ncr5390CtrlInit
(
    int * pAsc,           /* ptr to ASC info */
    int  scsiCtrlBusId,  /* SCSI bus ID of this ASC */
    UINT defaultSelTimeOut, /* default dev. select timeout (microsec) */
    int  scsiPriority     /* priority of task when doing SCSI I/O */
)
```

DESCRIPTION This routine initializes an ASC structure, after the structure is created with *ncr5390CtrlCreate()*. This structure must be initialized before the ASC can be used. It may be called more than once; however, it should be called only while there is no activity on the SCSI interface.

Before returning, this routine pulses RST (reset) on the SCSI bus, thus resetting all attached devices. The input parameters are:

pAsc

a pointer to the `NCR5390_SCSI_CTRL` structure created with *ncr5390CtrlCreate()*.

scsiCtrlBusId

the SCSI bus ID of the ASC, in the range 0 – 7. The ID is somewhat arbitrary; the value 7, or highest priority, is conventional.

defaultSelTimeOut

the timeout, in microseconds, for selecting a SCSI device attached to this controller. This value is used as a default if no timeout is specified in *scsiPhysDevCreate()*. The recommended value zero (0) specifies `SCSI_DEF_SELECT_TIMEOUT` (250 millisecc). The maximum timeout possible is approximately 2 seconds. Values exceeding this revert to the maximum.

scsiPriority

the priority to which a task is set when performing a SCSI transaction. Valid priorities are 0 to 255. Alternatively, the value -1 specifies that the priority should not be altered during SCSI transactions.

RETURNS OK, or ERROR if a parameter is out of range.

SEE ALSO `ncr5390Lib`, `scsiPhysDevCreate()`,

ncr5390Show()

NAME `ncr5390Show()` – display the values of all readable NCR5390 chip registers

SYNOPSIS

```
int ncr5390Show
(
    int * pScsiCtrl /* ptr to SCSI controller info */
)
```

DESCRIPTION This routine displays the state of the ASC registers in a user-friendly manner. It is useful primarily for debugging. It should not be invoked while another running process is accessing the SCSI controller.

EXAMPLE

```
-> ncr5390Show
REG #00 (Own ID           ) = 0x07
REG #01 (Control         ) = 0x00
REG #02 (Timeout Period ) = 0x20
REG #03 (Sectors         ) = 0x00
REG #04 (Heads           ) = 0x00
REG #05 (Cylinders MSB  ) = 0x00
REG #06 (Cylinders LSB  ) = 0x00
REG #07 (Log. Addr. MSB ) = 0x00
REG #08 (Log. Addr. 2SB ) = 0x00
REG #09 (Log. Addr. 3SB ) = 0x00
REG #0a (Log. Addr. LSB ) = 0x00
REG #0b (Sector Number  ) = 0x00
REG #0c (Head Number    ) = 0x00
REG #0d (Cyl. Number MSB) = 0x00
REG #0e (Cyl. Number LSB) = 0x00
REG #0f (Target LUN     ) = 0x00
REG #10 (Command Phase  ) = 0x00
REG #11 (Synch. Transfer) = 0x00
REG #12 (Xfer Count MSB ) = 0x00
```

```
REG #13 (Xfer Count 2SB ) = 0x00
REG #14 (Xfer Count LSB ) = 0x00
REG #15 (Destination ID ) = 0x03
REG #16 (Source ID      ) = 0x00
REG #17 (SCSI Status    ) = 0x42
REG #18 (Command        ) = 0x07
```

RETURNS OK, or ERROR if *pScsiCtrl* and *pSysScsiCtrl* are both NULL.

SEE ALSO *ncr5390Lib*

ncr710SingleStep()

NAME *ncr710SingleStep()* – perform a single-step

SYNOPSIS

```
void ncr710SingleStep
(
    SIOP * pSiop, /* pointer to SIOP info */
    BOOL  verbose /* show all registers */
)
```

DESCRIPTION This routine performs a single-step by writing the STD bit in the DCNTL register. The *pSiop* parameter is a pointer to the SIOP information. Before executing, enable the single-step facility by calling *ncr710StepEnable()*.

RETURNS N/A

SEE ALSO *ncr710CommLib*, *ncr710StepEnable()*

ncr710StepEnable()

NAME *ncr710StepEnable()* – enable/disable script single-step

SYNOPSIS

```
void ncr710StepEnable
(
    SIOP * pSiop, /* pointer to SIOP info */
    BOOL  boolValue /* TRUE/FALSE to enable/disable single step */
)
```

| | |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | This routine enables/disables the single-step facility on the chip. It also unmask/masks the single-step interrupt in the Dien register. Before executing any SCSI routines, enable the single-step facility by calling <i>ncr710StepEnable()</i> with <i>boolValue</i> set to TRUE. To disable, call it with <i>boolValue</i> set to FALSE. |
| RETURNS | N/A |
| SEE ALSO | <i>ncr710CommLib</i> , <i>ncr710SingleStep()</i> |

ne2000EndLoad()

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>ne2000EndLoad()</i> – initialize the driver and device |
| SYNOPSIS | <pre>END_OBJ* ne2000EndLoad (char* initString, /* String to be parsed by the driver. */ void* pBSP /* for BSP group */)</pre> |
| DESCRIPTION | <p>This routine initializes the driver and the device to the operational state. All of the device specific parameters are passed in the <i>initString</i>.</p> <p>The string contains the target specific parameters like this:</p> <p>"unit:register addr:int vector:int level:shmem addr:shmem size:shmem width"</p> |
| RETURNS | An END object pointer or NULL on error. |
| SEE ALSO | <i>ne2000End</i> |

ne2000Parse()

| | |
|-----------------|----------------------------------------------------------------------------------------------------|
| NAME | <i>ne2000Parse()</i> – parse the init string |
| SYNOPSIS | <pre>STATUS ne2000Parse (NE2000END_DEVICE * pDrvCtrl, char * initString)</pre> |

DESCRIPTION Parse the input string. Fill in values in the driver control structure.

The initialization string format is:
unit:adrs:vecnum:intLvl:byteAccess:usePromEnetAddr:offset

unit
 Device unit number, a small integer.

adrs
 Base address

vecNum
 Interrupt vector number (used with sysIntConnect)

intLvl
 Interrupt level (used with sysLanIntEnable)

byteAccess
 Use 8-bit access mode.

usePromEnetAddr
 get ethernet address from PROM.

offset
 offset for memory alignment

RETURNS OK or ERROR for invalid arguments.

SEE ALSO **ne2000End**

netBufLibInit()

NAME *netBufLibInit()* – initialize netBufLib

SYNOPSIS `STATUS netBufLibInit (void)`

DESCRIPTION This routine initializes **netBufLib**. If you defined `INCLUDE_NETWORK` in `configAll.h`, this configured VxWorks to include **netBufLib**.

RETURNS OK or ERROR.

SEE ALSO **netBufLib**

netClBlkFree()

NAME *netClBlkFree()* – free a **clBlk**-cluster construct back to the memory pool

SYNOPSIS

```
void netClBlkFree
(
    NET_POOL_ID pNetPool, /* pointer to the net pool */
    CL_BLK_ID   pClBlk    /* pointer to the clBlk to free */
)
```

DESCRIPTION This routine decrements the reference counter in the specified **clBlk**. If the reference count falls to zero, this routine frees both the **clBlk** and its associated cluster back to the specified memory pool.

RETURNS N/A

SEE ALSO **netBufLib**

netClBlkGet()

NAME *netClBlkGet()* – get a **clBlk**

SYNOPSIS

```
CL_BLK_ID netClBlkGet
(
    NET_POOL_ID pNetPool, /* pointer to the net pool */
    int         canWait   /* M_WAIT/M_DONTWAIT */
)
```

DESCRIPTION This routine gets a **clBlk** from the specified memory pool.

pNetPool

Expects a pointer to the pool from which you want a **clBlk**.

canWait

Expects either **M_WAIT** or **M_DONTWAIT**. If *canWait* is **M_WAIT**, this routine blocks until a **clBlk** is available. If *canWait* is **M_DONTWAIT** and no **clBlk** is immediately available, this routine returns immediately (no blocking) with a NULL value.

RETURNS **CL_BLK_ID** or a NULL if no **clBlk** was available.

SEE ALSO **netBufLib**

netClBlkJoin()

NAME *netClBlkJoin()* – join a cluster to a **clBlk** structure

SYNOPSIS

```
CL_BLK_ID netClBlkJoin
(
    CL_BLK_ID pClBlk, /* pointer to a cluster Blk */
    char *    pClBuf, /* pointer to a cluster buffer */
    int       size,   /* size of the cluster buffer */
    FUNCPTR   pFreeRtn, /* pointer to the free routine */
    int       arg1,   /* argument 1 of the free routine */
    int       arg2,   /* argument 2 of the free routine */
    int       arg3    /* argument 3 of the free routine */
)
```

DESCRIPTION This routine joins the previously reserved cluster specified by *pClBuf* to the previously reserved **clBlk** structure specified by *pClBlk*. The *size* parameter passes in the size of the cluster referenced in *pClBuf*. The arguments *pFreeRtn*, *arg1*, *arg2*, *arg3* set the values of the **pClFreeRtn**, **clFreeArg1**, **clFreeArg2**, and **clFreeArg1**, members of the specified **clBlk** structure.

RETURNS **CL_BLK_ID** or **NULL**.

SEE ALSO **netBufLib**

netClFree()

NAME *netClFree()* – free a cluster back to the memory pool

SYNOPSIS

```
void netClFree
(
    NET_POOL_ID pNetPool, /* pointer to the net pool */
    UCHAR *     pClBuf    /* pointer to the cluster buffer */
)
```

DESCRIPTION This routine returns the specified cluster buffer back to the specified memory pool.

RETURNS N/A

SEE ALSO **netBufLib**

netClPoolIdGet()

NAME *netClPoolIdGet()* – return a CL_POOL_ID for a specified buffer size

SYNOPSIS

```
CL_POOL_ID netClPoolIdGet
(
    NET_POOL_ID pNetPool, /* pointer to the net pool */
    int         bufSize,  /* size of the buffer */
    BOOL        bestFit   /* TRUE/FALSE */
)
```

DESCRIPTION This routine returns a CL_POOL_ID for a cluster pool containing clusters that match the specified *bufSize*. If *bestFit* is TRUE, this routine returns a CL_POOL_ID for a pool that contains clusters greater than or equal to *bufSize*. If *bestFit* is FALSE, this routine returns a CL_POOL_ID for a cluster from whatever cluster pool is available. If the memory pool specified by *pNetPool* contains only one cluster pool, *bestFit* should always be FALSE.

RETURNS CL_POOL_ID or NULL.

SEE ALSO **netBufLib**

netClusterGet()

NAME *netClusterGet()* – get a cluster from the specified cluster pool

SYNOPSIS

```
char * netClusterGet
(
    NET_POOL_ID pNetPool, /* pointer to the net pool */
    CL_POOL_ID  pClPool   /* ptr to the cluster pool */
)
```

DESCRIPTION This routine gets a cluster from the specified cluster pool *pClPool* within the specified memory pool *pNetPool*.

RETURNS This routine returns a character pointer to a cluster buffer or NULL if none was available.

SEE ALSO **netBufLib**

netDevCreate()

NAME *netDevCreate()* – create a remote file device

SYNOPSIS

```
STATUS netDevCreate
(
    char * devName, /* name of device to create */
    char * host,    /* host this device will talk to */
    int   protocol /* remote file access protocol 0 = RSH, 1 = FTP */
)
```

DESCRIPTION This routine creates a remote file device. Normally, a network device is created for each remote machine whose files are to be accessed. By convention, a network device name is the remote machine name followed by a colon ":". For example, for a UNIX host on the network whose name is "wrs", files can be accessed by creating a device called "wrs:". Files can be accessed via RSH as follows:

```
netDevCreate ("wrs:", "wrs", rsh);
```

The file /usr/dog on the UNIX system "wrs" can now be accessed as "wrs:/usr/dog" via RSH.

Before creating a device, the host must have already been created with *hostAdd()*.

RETURNS OK or ERROR.

SEE ALSO *netDrv*, *hostAdd()*

netDrv()

NAME *netDrv()* – install the network remote file driver

SYNOPSIS STATUS *netDrv* (void)

DESCRIPTION This routine initializes and installs the network driver. It must be called before other network remote file functions are performed. It is called automatically when the configuration macro `INCLUDE_NETWORK` is defined.

RETURNS OK or ERROR.

SEE ALSO *netDrv*

netHelp()

NAME *netHelp()* – print a synopsis of network routines

SYNOPSIS `void netHelp (void)`

DESCRIPTION This command prints a brief synopsis of network facilities that are typically called from the shell.

```
hostAdd      "hostname", "inetaddr" - add a host to remote host table;
                                     "inetaddr" must be in standard
                                     Internet address format e.g.
"90.0.0.4"
hostShow     - print current remote host table
netDevCreate "devname", "hostname", protocol
                                     - create an I/O device to access
                                     files on the specified host
                                     (protocol 0=rsh, 1=ftp)
routeAdd     "destaddr", "gateaddr" - add route to route table
routeDelete  "destaddr", "gateaddr" - delete route from route table
routeShow   - print current route table
iam          "usr" [, "passwd"]      - specify the user name by which
                                     you will be known to remote
                                     hosts (and optional password)
whoami       - print the current remote ID
rlogin       "host"                 - log in to a remote host;
                                     "host" can be inet address or
                                     host name in remote host table
ifShow       ["ifname"]             - show info about network interfaces
inetstatShow - show all Internet protocol sockets
tcpstatShow - show statistics for TCP
udpstatShow  - show statistics for UDP
ipstatShow   - show statistics for IP
icmpstatShow - show statistics for ICMP
arptabShow   - show a list of known ARP entries
mbufShow     - show mbuf statistics
EXAMPLE:     -> hostAdd "wrs", "90.0.0.2"
              -> netDevCreate "wrs:", "wrs", 0
              -> iam "fred"
              -> copy <wrs:/etc/passwd /* copy file from host "wrs" */
              -> rlogin "wrs" /* rlogin to host "wrs" */
```

RETURNS N/A

netMblkClChainFree()

NAME *netMblkClChainFree()* – free a chain of **mBlk-clBlk**-cluster constructs

SYNOPSIS `void netMblkClChainFree`
 (
 M_BLK_ID pMblk /* pointer to the mBlk */
)

DESCRIPTION For the specified chain of **mBlk-clBlk**-cluster constructs, this routine frees all the **mBlk** structures back to the specified memory pool. It also decrements the reference count in all the **clBlk** structures. If the reference count in a **clBlk** falls to zero, this routine also frees that **clBlk** and its associated cluster back to the specified memory pool.

RETURNS N/A

ERRNO **S_netBufLib_MBLK_INVALID**

SEE ALSO **netBufLib**

netMblkClFree()

NAME *netMblkClFree()* – free an **mBlk-clBlk**-cluster construct

SYNOPSIS `M_BLK_ID netMblkClFree`
 (
 M_BLK_ID pMblk /* pointer to the mBlk */
)

DESCRIPTION For the specified **mBlk-clBlk**-cluster construct, this routine frees the **mBlk** back to the specified memory pool. It also decrements the reference count in the **clBlk** structure. If the reference count falls to zero, no other **mBlk** structure reference this **clBlk**. In that case,

this routine also frees the **cBlk** structure and its associated cluster back to the specified memory pool.

| | |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| RETURNS | If the specified mBlk was part of an mBlk chain, this routine returns a pointer to the next mBlk . Otherwise, it returns a NULL. |
| ERRNO | <code>S_netBufLib_MBLK_INVALID</code> |
| SEE ALSO | <code>netBufLib</code> |

netMblkClGet()

NAME *netMblkClGet()* – get a **cBlk**-cluster and join it to the specified **mBlk**

SYNOPSIS

```

STATUS netMblkClGet
(
    NET_POOL_ID pNetPool, /* pointer to the net pool */
    M_BLK_ID    pMblk,    /* mBlk to embed the cluster in */
    int         bufSize,  /* size of the buffer to get */
    int         canWait,  /* wait or dontwait */
    BOOL        bestFit   /* TRUE/FALSE */
)

```

DESCRIPTION This routine gets a **cBlk**-cluster construct from the specified memory pool and joins it to the specified **mBlk** structure. This creates an **mBlk-cBlk**-cluster construct that you can use to pass data across the layers of the network stack.

pNetPool

Expects a pointer to the memory pool from which you want to get a free **cBlk**-cluster construct.

pMblk

Expects a pointer to the **mBlk** structure (previously allocated) to which you want to join the retrieved **cBlk**-cluster construct.

bufSize

Expects the size, in bytes, of the cluster in the **cBlk**-cluster construct.

canWait

Expects either `M_WAIT` or `M_DONTWAIT`. If *canWait* is `M_WAIT`, this routine blocks until a **cBlk**-cluster construct is available. If *canWait* is `M_DONTWAIT` and no **cBlk**-cluster construct is immediately available, this routine returns immediately (no blocking) with an ERROR value.

netMblkClJoin()*bestFit*

Expects either TRUE or FALSE. If *bestFit* is TRUE and a cluster of the exact size is unavailable, this routine gets a larger cluster (if available). If *bestFit* is FALSE and an exact size cluster is unavailable, this routine gets either a smaller or a larger cluster (depending on what is available). Otherwise, it returns immediately with an ERROR value. For memory pools containing only one cluster size, *bestFit* should always be set to FALSE.

RETURNS OK or ERROR.

ERRNO S_netBufLib_CLSIZE_INVALID

SEE ALSO netBufLib

netMblkClJoin()

NAME *netMblkClJoin()* – join an **mBlk** to a **clBlk**-cluster construct

SYNOPSIS

```
M_BLK_ID netMblkClJoin
(
    M_BLK_ID pMblk, /* pointer to an mBlk */
    CL_BLK_ID pClBlk /* pointer to a cluster Blk */
)
```

DESCRIPTION This routine joins the previously reserved **mBlk** referenced in *pMblk* to the **clBlk**-cluster construct referenced in *pClBlk*. Internally, this routine sets the **M_EXT** flag in **mBlk.mBlkHdr.mFlags**. It also and sets the **mBlk.mBlkHdr.mData** to point to the start of the data in the cluster.

RETURNS M_BLK_ID or NULL.

SEE ALSO netBufLib

netMblkDup()

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>netMblkDup()</i> – duplicate an mBlk |
| SYNOPSIS | <pre>M_BLK_ID netMblkDup (M_BLK_ID pSrcMblk, /* pointer to source mBlk */ M_BLK_ID pDestMblk /* pointer to the destination mBlk */)</pre> |
| DESCRIPTION | This routine copies the references from a source mBlk in an mBlk-clBlk -cluster construct to a stand-alone mBlk . This lets the two mBlk structures share the same clBlk -cluster construct. This routine also increments the reference count in the shared clBlk . The <i>pSrcMblk</i> expects a pointer to the source mBlk . The <i>pDestMblk</i> parameter expects a pointer to the destination mBlk . |
| RETURNS | A pointer to the destination mBlk or NULL if the source mBlk referenced in <i>pSrcMblk</i> is not part of a valid mBlk-clBlk -cluster construct. |
| SEE ALSO | netBufLib |

netMblkFree()

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>netMblkFree()</i> – free an mBlk back to its memory pool |
| SYNOPSIS | <pre>void netMblkFree (NET_POOL_ID pNetPool, /* pointer to the net pool */ M_BLK_ID pMblk /* mBlk to free */)</pre> |
| DESCRIPTION | This routine frees the specified mBlk back to the specified memory pool. |
| RETURNS | N/A |
| SEE ALSO | netBufLib |

netMblkGet()

netMblkGet()**NAME** *netMblkGet()* – get an mBlk

SYNOPSIS `M_BLK_ID netMblkGet`

```
(
    NET_POOL_ID pNetPool, /* pointer to the net pool */
    int         canWait,  /* M_WAIT/M_DONTWAIT */
    UCHAR       type      /* mBlk type */
)
```

DESCRIPTION This routine gets a **mBlk** from the specified memory pool.*pNetPool*Expects a pointer to the pool from which you want an **mBlk**.*canWait*Expects either **M_WAIT** or **M_DONTWAIT**. If *canWait* is **M_WAIT**, this routine blocks until an **mBlk** is available. If *canWait* is **M_DONTWAIT** and no **mBlk** is immediately available, this routine returns immediately (no blocking) with a NULL value.*type*Expects the type value that you want to associate with the returned **mBlk**.**RETURNS** **M_BLK_ID**, or a NULL if no **mBlk** was available.**ERRNO** **S_netBufLib_MBLK_INVALID****SEE ALSO** **netBufLib**

netMblkToBufCopy()**NAME** *netMblkToBufCopy()* – copy data from an mBlk to a buffer

SYNOPSIS `int netMblkToBufCopy`

```
(
    M_BLK_ID pMblk, /* pointer to an mBlk */
    char *   pBuf,  /* pointer to the buffer to copy */
    FUNCPTR pCopyRtn /* function pointer for copy routine */
)
```

DESCRIPTION This routine copies data from the **mBlk** chain referenced in *pMblk* to the buffer referenced in *pBuf*. It is assumed that *pBuf* points to enough memory to contain all the data in the entire **mBlk** chain. The argument *pCopyRtn* expects either a NULL or a function pointer to a copy routine. The arguments passed to the copy routine are source pointer, destination pointer and the length of data to copy. If *pCopyRtn* is NULL, *netMblkToBufCopy()* uses a default routine to extract the data from the chain.

RETURNS The length of data copied or zero.

SEE ALSO **netBufLib**

netPoolDelete()

NAME *netPoolDelete()* – delete a memory pool

SYNOPSIS

```
STATUS netPoolDelete
(
    NET_POOL_ID pNetPool /* pointer to a net pool */
)
```

DESCRIPTION This routine deletes the specified **netBufLib**-managed memory pool.

RETURNS OK or ERROR.

ERRNO S_netBufLib_NETPOOL_INVALID

SEE ALSO **netBufLib**

netPoolInit()

NAME *netPoolInit()* – initialize a **netBufLib**-managed memory pool

SYNOPSIS

```
STATUS netPoolInit
(
    NET_POOL_ID    pNetPool,          /* pointer to a net pool */
    M_CL_CONFIG *  pMclBlkConfig,     /* pointer to a mBlk configuration */
    CL_DESC *      pClDescTbl,        /* pointer to cluster desc table */
    int            clDescTblNumEnt,   /* number of cluster desc entries */
    POOL_FUNC *    pFuncTbl           /* pointer to pool function table */
)
```

netPoolInit()**DESCRIPTION**

Call this routine to set up a **netBufLib**-managed memory pool. Within this pool, **netPoolInit()** organizes several sub-pools: one for **mBlk** structures, one for **cBlk** structures, and as many cluster sub-pools as there are cluster sizes. As input, this routine expects the following parameters:

pNetPool

Expects a **NET_POOL_ID** that points to a previously allocated **NET_POOL** structure. You need not initialize any values in this structure. That is handled by **netPoolInit()**.

pMClBlkConfig

Expects a pointer to a previously allocated and initialized **M_CL_CONFIG** structure. Within this structure, you must provide four values: **mBlkNum**, a count of **mBlk** structures; **cBlkNum**, a count of **cBlk** structures; **memArea**, a pointer to an area of memory that can contain all the **mBlk** and **cBlk** structures; and **memSize**, the size of that memory area. For example, you can set up an **M_CL_CONFIG** structure as follows:

```
M_CL_CONFIG mClBlkConfig = /* mBlk, cBlk configuration table */
{
    mBlkNum      cBlkNum      memArea      memSize
    -----      ----      -
    400,         245,         0xfe000000,    21260
};
```

You can calculate the **memArea** and **memSize** values. Such code could first define a table as shown above, but set both **memArea** and **memSize** as follows:

```
mClBlkConfig.memSize = (mClBlkConfig.mBlkNum * (M_BLK_SZ + sizeof(long))) +
    (mClBlkConfig.cBlkNum * CL_BLK_SZ);
```

You can set the **memArea** value to a pointer to private memory, or you can reserve the memory with a call to **malloc()**. For example:

```
mClBlkConfig.memArea = malloc(mClBlkConfig.memSize);
```

The **netBufLib.h** file defines **M_BLK_SZ** as:

```
sizeof(struct mBlk)
```

Currently, this evaluates to 32 bytes. Likewise, this file defines **CL_BLK_SZ** as:

```
sizeof(struct cBlk)
```

Currently, this evaluates to 32 bytes.

When choosing values for **mBlkNum** and **cBlkNum**, remember that you need as many **cBlk** structures as you have clusters (data buffers). You also need at least as many **mBlk** structures as you have **cBlk** structures, but you will most likely need more. That is because **netBufLib** shares buffers by letting multiple **mBlk** structures join to the same **cBlk** and thus to its underlying cluster. The **cBlk** keeps a count of the number of **mBlk** structures that reference it.

pCIDescTbl

Expects a pointer to a table of previously allocated and initialized **CL_DESC** structures. Each structure in this table describes a single cluster pool. You need a dedicated cluster pool for each cluster size you want to support. Within each **CL_DESC** structure, you must provide four values: **clusterSize**, the size of a cluster in this cluster pool; **num**, the number of clusters in this cluster pool; **memArea**, a pointer to an area of memory that can contain all the clusters; and **memSize**, the size of that memory area.

Thus, if you need to support six different cluster sizes, this parameter must point to a table containing six **CL_DESC** structures. For example, consider the following:

```
CL_DESC clDescTbl [] = /* cluster descriptor table */
{
/*
clusterSize      num      memArea      memSize
-----
*/
{64,             100,     0x10000,     6800},
{128,            50,      0x20000,     6600},
{256,            50,      0x30000,     13000},
{512,            25,      0x40000,     12900},
{1024,           10,      0x50000,     10280},
{2048,           10,      0x60000,     20520}
};
```

As with the **memArea** and **memSize** members in the **M_CL_CONFIG** structure, you can set these members of the **CL_DESC** structures by calculation after you create the table. The formula would be as follows:

```
clDescTbl[n].memSize =
    (clDescTbl[n].num * (clDescTbl[n].clusterSize + sizeof(long)));
```

The **memArea** member can point to a private memory area that you know to be available for storing clusters, or you can use *malloc()*.

```
clDescTbl[n].memArea = malloc( clDescTbl[n].memSize );
```

Valid cluster sizes range from 64 bytes to 65536 bytes. If there are multiple cluster pools, valid sizes are further restricted to powers of two (for example, 64, 128, 256, and so on). If there is only one cluster pool (as is often the case for the memory pool specific to a single device driver), there is no power of two restriction. Thus, the cluster can be of any size between 64 bytes and 65536 bytes on 4-byte alignment. A typical buffer size for Ethernet devices is 1514 bytes. However, because a cluster size requires a 4-byte alignment, the cluster size for this Ethernet buffer would have to be increased to at least 1516 bytes.

clDescTblNumEnt

Expects a count of the elements in the **CL_DESC** table referenced by the *pCIDescTbl* parameter. This is a count of the number of cluster pools. You can get this value

netPoolShow()

using the NELEMENTS macro defined in `vxWorks.h`. For example:

```
int clDescTblNumEnt = (NELEMENTS(clDescTbl));
```

pFuncTbl

Expects a NULL or a pointer to a function table. This table contains pointers to the functions used to manage the buffers in this memory pool. Using a NULL for this parameter tells `netBufLib` to use its default function table. If you opt for the default function table, every `mBlk` and every cluster is prepended by a 4-byte header (which is why the size calculations above for clusters and `mBlk` structures contained an extra `sizeof(long)`). However, users need not concern themselves with this header when accessing these buffers. The returned pointers from functions such as `netClusterGet()` return pointers to the start of data, which is just after the header.

Assuming you have set up the configuration tables as shown above, a typical call to `netPoolInit()` would be as follows:

```
int clDescTblNumEnt = (NELEMENTS(clDescTbl));
NET_POOL netPool;
NET_POOL_ID pNetPool = &netPool;
if (netPoolInit (pNetPool, &mClBlkConfig, &clDescTbl [0],
clDescTblNumEnt,
NULL) != OK)
return (ERROR);
```

RETURNS

OK or ERROR.

## *nfsAuthUnixSet()*

|                    |                                                                                                                                                                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>nfsAuthUnixSet()</i> – set the NFS UNIX authentication parameters                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <pre>void nfsAuthUnixSet (     char * machname, /* host machine */     int   uid,       /* user ID */     int   gid,       /* group ID */     int   ngids,     /* number of group IDs */     int *  aup_gids  /* array of group IDs */ )</pre>                                   |
| <b>DESCRIPTION</b> | This routine sets UNIX authentication parameters. It is initially called by <i>usrNetInit()</i> in <i>usrConfig.c</i> . <b><i>machname</i></b> should be set with the name of the mounted system (i.e. the target name itself) to distinguish hosts from hosts on a NFS network. |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                              |
| <b>SEE ALSO</b>    | <i>nfsLib</i> , <i>nfsAuthUnixPrompt()</i> , <i>nfsAuthUnixShow()</i> , <i>nfsAuthUnixGet()</i> , <i>nfsIdSet()</i> , <i>usrConfig</i>                                                                                                                                           |

---

## *nfsAuthUnixShow()*

|                    |                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>nfsAuthUnixShow()</i> – display the NFS UNIX authentication parameters                                                      |
| <b>SYNOPSIS</b>    | <pre>void nfsAuthUnixShow (void)</pre>                                                                                         |
| <b>DESCRIPTION</b> | This routine displays the parameters set by <i>nfsAuthUnixSet()</i> or <i>nfsAuthUnixPrompt()</i> .                            |
| <b>EXAMPLE</b>     | <pre>-&gt; nfsAuthUnixShow machine name = yuba user ID      = 2001 group ID     = 100 group [0]    = 100 value = 1 = 0x1</pre> |
| <b>RETURNS</b>     | N/A                                                                                                                            |
| <b>SEE ALSO</b>    | <i>nfsLib</i> , <i>nfsAuthUnixPrompt()</i> , <i>nfsAuthUnixSet()</i> , <i>nfsAuthUnixGet()</i> , <i>nfsIdSet()</i>             |

## *nfsDevInfoGet()*

- NAME** *nfsDevInfoGet()* – read configuration information from the requested NFS device
- SYNOPSIS**
- ```
STATUS nfsDevInfoGet
(
    unsigned long  nfsDevHandle, /* NFS device handle */
    NFS_DEV_INFO * pnfsInfo      /* ptr to struct to hold config info */
)
```
- DESCRIPTION** This routine accesses the NFS device specified in the parameter *nfsDevHandle* and fills in the structure pointed to by *pnfsInfo*.
- RETURNS** OK if *pnfsInfo* information is valid, otherwise ERROR.
- SEE ALSO** *nfsDrv*, *nfsDevListGet()*
-

nfsDevListGet()

- NAME** *nfsDevListGet()* – create list of all the NFS devices in the system
- SYNOPSIS**
- ```
int nfsDevListGet
(
 unsigned long nfsDevList[], /* NFS dev list of handles */
 int listSize /* no. of elements available in the list */
)
```
- DESCRIPTION** This routine fills the array *nfsDevList* up to *listSize*, with handles to NFS devices currently in the system.
- RETURNS** The number of entries filled in the *nfsDevList* array.
- SEE ALSO** *nfsDrv*, *nfsDevInfoGet()*

---

## *nfsDevShow()*

- NAME** *nfsDevShow()* – display the mounted NFS devices
- SYNOPSIS** `void nfsDevShow (void)`
- DESCRIPTION** This routine displays the device names and their associated NFS file systems.
- EXAMPLE**
- ```

-> nfsDevShow
device name          file system
-----
/yuba1/              yuba:/yuba1
/wrs1/               wrs:/wrs1

```
- RETURNS** N/A
- SEE ALSO** *nfsDrv*

nfsdInit()

- NAME** *nfsdInit()* – initialize the NFS server
- SYNOPSIS**
- ```

STATUS nfsdInit
(
 int nServers, /* the number of NFS servers to create */
 int nExportedFs, /* maximum number of exported file systems */
 int priority, /* the priority for the NFS servers */
 FUNCPTR authHook, /* authentication hook */
 FUNCPTR mountAuthHook, /* authentication hook for mount daemon */
 int options /* currently unused */
)

```
- DESCRIPTION** This routine initializes the NFS server. *nServers* specifies the number of tasks to be spawned to handle NFS requests. *priority* is the priority that those tasks will run at. *authHook* is a pointer to an authorization routine. *mountAuthHook* is a pointer to a similar routine, passed to *mountdInit()*. *options* is provided for future expansion.
- Normally, no authorization is performed by either *mountd* or *nfsd*. If you want to add authorization, set *authHook* to a function pointer to a routine declared as follows:

***nfsDrv()***

*nfsstat* routine

```
(
 int progNum, /* RPC program number */
 int versNum, /* RPC program version number */
 int procNum, /* RPC procedure number */
 struct sockaddr_in clientAddr, /* address of the client */
 NFSD_ARGUMENT * nfsdArg /* argument of the call */
)
```

The *authHook* routine should return NFS\_OK if the request is authorized, and NFSERR\_ACCES if not. (NFSERR\_ACCES is not required; any legitimate NFS error code can be returned.)

See *mountdInit()* for documentation on *mountAuthHook*. Note that *mountAuthHook* and *authHook* can point to the same routine. Simply use the *progNum*, *versNum*, and *procNum* fields to decide whether the request is an NFS request or a mountd request.

**RETURNS** OK, or ERROR if the NFS server cannot be started.

**SEE ALSO** *nfsdLib*, *nfsExport()*, *mountdInit()*

***nfsDrv()***

**NAME** *nfsDrv()* – install the NFS driver

**SYNOPSIS** STATUS *nfsDrv* (void)

**DESCRIPTION** This routine initializes and installs the NFS driver. It must be called before any reads, writes, or other NFS calls. This is done automatically when the configuration macro INCLUDE\_NFSis defined.

**RETURNS** OK, or ERROR if there is no room for the driver.

**SEE ALSO** *nfsDrv*

***nfsDrvNumGet()***

**NAME** *nfsDrvNumGet()* – return the IO system driver number for the nfs driver

**SYNOPSIS** int *nfsDrvNumGet* (void)

**DESCRIPTION** This routine returns the nfs driver number allocated by iosDrvInstall during the nfs driver initialization. If the nfs driver has yet to be initialized, or if initialization failed, nfsDrvNumGet will return ERROR.

**RETURNS** the nfs driver number or ERROR

**SEE ALSO** nfsDrv

---

## *nfsdStatusGet()*

**NAME** *nfsdStatusGet()* – get the status of the NFS server

**SYNOPSIS**

```
STATUS nfsdStatusGet
(
 NFS_SERVER_STATUS * serverStats /* pointer to status structure */
)
```

**DESCRIPTION** This routine gets status information about the NFS server.

**RETURNS** OK, or ERROR if the information cannot be obtained.

**SEE ALSO** nfsdLib

---

## *nfsdStatusShow()*

**NAME** *nfsdStatusShow()* – show the status of the NFS server

**SYNOPSIS**

```
STATUS nfsdStatusShow
(
 int options /* unused */
)
```

**DESCRIPTION** This routine shows status information about the NFS server.

**RETURNS** OK, or ERROR if the information cannot be obtained.

**SEE ALSO** nfsdLib

## *nfsExport()*

**NAME** *nfsExport()* – specify a file system to be NFS exported

**SYNOPSIS**

```
STATUS nfsExport
(
 char * directory, /* Directory to export - FS must support NFS */
 int id, /* ID number for file system */
 BOOL readOnly, /* TRUE if file system is exported read-only */
 int options /* Reserved for future use - set to 0 */
)
```

**DESCRIPTION** This routine makes a file system available for mounting by a client. The client should be in the local host table (see *hostAdd()*), although this is not required.

The *id* parameter can either be set to a specific value, or to 0. If it is set to 0, an ID number is assigned sequentially. Every time a file system is exported, it must have the same ID number, or clients currently mounting the file system will not be able to access files.

To display a list of exported file systems, use:

```
-> nfsExportShow "localhost"
```

**RETURNS** OK, or ERROR if the file system could not be exported.

**SEE ALSO** *mountLib*, *nfsLib*, *nfsExportShow()*, *nfsUnexport()*

---

## *nfsExportShow()*

**NAME** *nfsExportShow()* – display the exported file systems of a remote host

**SYNOPSIS**

```
STATUS nfsExportShow
(
 char * hostName /* host machine to show exports for */
)
```

**DESCRIPTION** This routine displays the file systems of a specified host and the groups that are allowed to mount them.

**EXAMPLE**

```
-> nfsExportShow "wrs"
/d0 staff
/d1 staff eng
```

```

/d2 eng
/d3
value = 0 = 0x0

```

**RETURNS** OK or ERROR.

**SEE ALSO** *nfsLib*

---

## *nfsHelp()*

**NAME** *nfsHelp()* – display the NFS help menu

**SYNOPSIS** `void nfsHelp (void)`

**DESCRIPTION** This routine displays a summary of NFS facilities typically called from the shell:

|                                                          |                                                                              |
|----------------------------------------------------------|------------------------------------------------------------------------------|
| <code>nfsHelp</code>                                     | Print this list                                                              |
| <code>netHelp</code>                                     | Print general network help list                                              |
| <code>nfsMount "host", "filesystem" [, "devname"]</code> | Create device with<br>file system/directory from host                        |
| <code>nfsUnmount "devname"</code>                        | Remove an NFS device                                                         |
| <code>nfsAuthUnixShow</code>                             | Print current UNIX authentication                                            |
| <code>nfsAuthUnixPrompt</code>                           | Prompt for UNIX authentication                                               |
| <code>nfsIdSet id</code>                                 | Set user ID for UNIX authentication                                          |
| <code>nfsDevShow</code>                                  | Print list of NFS devices                                                    |
| <code>nfsExportShow "host"</code>                        | Print a list of NFS file systems which<br>are exported on the specified host |
| <code>mkdir "dirname"</code>                             | Create directory                                                             |
| <code>rm "file"</code>                                   | Remove file                                                                  |

EXAMPLE: `-> hostAdd "wrs", "90.0.0.2"`  
`-> nfsMount "wrs", "/disk0/path/mydir", "/mydir/"`  
`-> cd "/mydir/"`  
`-> nfsAuthUnixPrompt /* fill in user ID, etc. */`  
`-> ls /* list /disk0/path/mydir */`  
`-> copy < foo /* copy foo to standard out */`  
`-> ld < foo.o /* load object module foo.o */`  
`-> nfsUnmount "/mydir/" /* remove NFS device /mydir/ */`

**RETURNS** N/A

**SEE ALSO** *nfsLib*

***nfsIdSet()***

---

***nfsIdSet()***

|                    |                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>nfsIdSet()</i> – set the ID number of the NFS UNIX authentication parameters                                                                                                      |
| <b>SYNOPSIS</b>    | <pre>void nfsIdSet (     int uid /* user ID on host machine */ )</pre>                                                                                                               |
| <b>DESCRIPTION</b> | This routine sets only the UNIX authentication user ID number. For most NFS permission needs, only the user ID needs to be changed. Set <i>uid</i> to the user ID on the NFS server. |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                  |
| <b>SEE ALSO</b>    | <i>nfsLib</i> , <i>nfsAuthUnixPrompt()</i> , <i>nfsAuthUnixShow()</i> , <i>nfsAuthUnixSet()</i> , <i>nfsAuthUnixGet()</i>                                                            |

---

***nfsMount()***

|                    |                                                                                                                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>nfsMount()</i> – mount an NFS file system                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <pre>STATUS nfsMount (     char * host,          /* name of remote host */     char * fileSystem,  /* name of remote directory to mount */     char * localName    /* local device name for remote dir (NULL = use */                        /* name) */ )</pre>                                          |
| <b>DESCRIPTION</b> | This routine mounts a remote file system. It creates a local device <i>localName</i> for a remote file system on a specified host. The host must have already been added to the local host table with <i>hostAdd()</i> . If <i>localName</i> is NULL, the local name will be the same as the remote name. |
| <b>RETURNS</b>     | OK, or ERROR if the driver is not installed, <i>host</i> is invalid, or memory is insufficient.                                                                                                                                                                                                           |
| <b>SEE ALSO</b>    | <i>nfsDrv</i> , <i>nfsUnmount()</i> , <i>hostAdd()</i>                                                                                                                                                                                                                                                    |

---

## *nfsMountAll()*

|                    |                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>nfsMountAll()</i> – mount all file systems exported by a specified host                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <pre>STATUS nfsMountAll (     char * host,          /* name of remote host */     char * clientName, /* name of client specified in access list */     BOOL  quiet          /* FALSE = print names of file systems mounted */ )</pre>                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>This routine mounts the file systems exported by <i>host</i> which are marked as accessible either by all clients or only by <i>clientName</i>. The <i>nfsMount()</i> routine is called to mount each file system. This creates a local device for each mounted file system that has the same name as the file system.</p> <p>The file systems are listed to standard output as they are mounted.</p> |
| <b>RETURNS</b>     | OK, or ERROR if any mount fails.                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SEE ALSO</b>    | <i>nfsDrv</i> , <i>nfsMount()</i>                                                                                                                                                                                                                                                                                                                                                                        |

## *nfsUnexport()*

|                    |                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>nfsUnexport()</i> – remove a file system from the list of exported file systems                                                                                                                         |
| <b>SYNOPSIS</b>    | <pre>STATUS nfsUnexport (     char * dirName /* Name of the directory to unexport */ )</pre>                                                                                                               |
| <b>DESCRIPTION</b> | <p>This routine removes a file system from the list of file systems exported from the target. Any client attempting to mount a file system that is not exported will receive an error (NFSERR_ACCESS).</p> |
| <b>RETURNS</b>     | OK, or ERROR if the file system could not be removed from the exports list.                                                                                                                                |
| <b>ERRNO</b>       | ENOENT                                                                                                                                                                                                     |
| <b>SEE ALSO</b>    | <i>mountLib</i> , <i>nfsLib</i> , <i>nfsExportShow()</i> , <i>nfsExport()</i>                                                                                                                              |

## ***nfsUnmount()***

- NAME** *nfsUnmount()* – unmount an NFS device
- SYNOPSIS**
- ```
STATUS nfsUnmount
(
    char * localName /* local of nfs device */
)
```
- DESCRIPTION** This routine unmounts file systems that were previously mounted via NFS.
- RETURNS** OK, or ERROR if *localName* is not an NFS device or cannot be mounted.
- SEE ALSO** *nfsDrv*, *nfsMount()*
-

nicEndLoad()

- NAME** *nicEndLoad()* – initialize the driver and device
- SYNOPSIS**
- ```
END_OBJ* nicEvbEndLoad
(
 char* initString /* string to be parse by the driver */
)
```
- DESCRIPTION** This routine initializes the driver and the device to the operational state. All of the device-specific parameters are passed in *initString*, which expects a string of the following format:
- ```
unit:base_addr:int_vector:int_level
```
- This routine can be called in two modes. If it is called with an empty but allocated string, it places the name of this device (that is, "ln") into the *initString* and returns 0.
- If the string is allocated and not empty, the routine attempts to load the driver using the values specified in the string.
- RETURNS** An END object pointer, or NULL on error, or 0 and the name of the device if the *initString* was NULL.
- SEE ALSO** *nicEvbEnd*

nicEvbattach()

NAME *nicEvbattach()* – publish and initialize the **nicEvb** network interface driver

SYNOPSIS

```
STATUS nicEvbattach
(
    int          unit, /* unit number */
    NIC_DEVICE * pNic, /* address of NIC chip */
    int          ivec /* interrupt vector to use */
)
```

DESCRIPTION This routine publishes the **nicEvb** interface by filling in a network interface record and adding this record to the system list. It also initializes the driver and the device to the operational state.

RETURNS OK, or ERROR if the receive buffer memory could not be allocated.

SEE ALSO *if_nicEvb*

nicEvbInitParse()

NAME *nicEvbInitParse()* – parse the initialization string

SYNOPSIS

```
STATUS nicEvbInitParse
(
    NICEVB_END_DEVICE * pDrvCtrl,
    char *             initString
)
```

DESCRIPTION Parse the input string. Fill in values in the driver control structure. The initialization string format is: *unit:base_adrs:vecnum:intLvl*

unit
Device unit number, a small integer.

base_adrs
Base address for NIC device

vecNum
Interrupt vector number (used with *sysIntConnect()*).

nicTxStartup()

intLvl

Interrupt level.

RETURNS OK, or ERROR if any arguments are invalid.

SEE ALSO `nicEvbEnd`

nicTxStartup()

NAME `nicTxStartup()` – the driver’s actual output routine

SYNOPSIS

```
#ifdef BSD43_DRIVER LOCAL STATUS nicTxStartup
(
    int unit
)
```

DESCRIPTION This routine accepts outgoing packets from the `if_snd` queue, and then gains exclusive access to the DMA (through a mutex semaphore), then calls `nicTransmit()` to send the packet out onto the interface.

RETURNS OK, or ERROR if the packet could not be transmitted.

SEE ALSO `if_nicEvb`

npc()

NAME `npc()` – return the contents of the next program counter (SPARC)

SYNOPSIS

```
int npc
(
    int taskId /* task ID, 0 means default task */
)
```

DESCRIPTION This command extracts the contents of the next program counter from the TCB of a specified task. If `taskId` is omitted or 0, the current default task is assumed.

RETURNS The contents of the next program counter.

SEE ALSO `dbgArchLib`, `ti()`

ns16550DevInit()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>ns16550DevInit()</i> – initialize an NS16550 channel |
| SYNOPSIS | <pre>void ns16550DevInit (NS16550_CHAN * pChan /* pointer to channel */)</pre> |
| DESCRIPTION | This routine initializes some SIO_CHAN function pointers and then resets the chip in a quiescent state. Before this routine is called, the BSP must already have initialized all the device addresses, etc. in the NS16550_CHAN structure. |
| RETURNS | N/A |
| SEE ALSO | <i>ns16550Sio</i> |

ns16550Int()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>ns16550Int()</i> – interrupt level processing |
| SYNOPSIS | <pre>void ns16550Int (NS16550_CHAN * pChan /* pointer to channel */)</pre> |
| DESCRIPTION | <p>This routine handles four sources of interrupts from the UART. They are prioritized in the following order by the Interrupt Identification Register: Receiver Line Status, Received Data Ready, Transmit Holding Register Empty and Modem Status.</p> <p>When a modem status interrupt occurs, the transmit interrupt is enabled if the CTS signal is TRUE.</p> |
| RETURNS | N/A |
| SEE ALSO | <i>ns16550Sio</i> |

ns16550IntEx()

| | |
|--------------------|------------------------------------------------------------------------------------|
| NAME | <i>ns16550IntEx()</i> – miscellaneous interrupt processing |
| SYNOPSIS | <pre>void ns16550IntEx (NS16550_CHAN * pChan /* pointer to channel */)</pre> |
| DESCRIPTION | This routine handles miscellaneous interrupts on the UART. Not implemented yet. |
| RETURNS | N/A |
| SEE ALSO | ns16550Sio |

ns16550IntRd()

| | |
|--------------------|------------------------------------------------------------------------------------|
| NAME | <i>ns16550IntRd()</i> – handle a receiver interrupt |
| SYNOPSIS | <pre>void ns16550IntRd (NS16550_CHAN * pChan /* pointer to channel */)</pre> |
| DESCRIPTION | This routine handles read interrupts from the UART. |
| RETURNS | N/A |
| SEE ALSO | ns16550Sio |

ns16550IntWr()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>ns16550IntWr()</i> – handle a transmitter interrupt |
| SYNOPSIS | <pre>void ns16550IntWr (NS16550_CHAN * pChan /* pointer to channel */)</pre> |
| DESCRIPTION | <p>This routine handles write interrupts from the UART. It reads a character and puts it in the transmit holding register of the device for transfer.</p> <p>If there are no more characters to transmit, transmission is disabled by clearing the transmit interrupt enable bit in the IER(int enable register).</p> |
| RETURNS | N/A |
| SEE ALSO | <i>ns16550Sio</i> |

ntInt()

| | |
|--------------------|--------------------------------------------------------------------------------------------|
| NAME | <i>ntInt()</i> – handle controller interrupt |
| SYNOPSIS | <pre>void ntInt (NTEND_DEVICE * pDrvCtrl)</pre> |
| DESCRIPTION | This routine is called at interrupt level in response to an interrupt from the controller. |
| RETURNS | N/A. |
| SEE ALSO | <i>ntEnd</i> |

ntLoad()

ntLoad()

NAME *ntLoad()* – initialize the driver and device

SYNOPSIS

```
END_OBJ* ntLoad
(
    char* initString, /* String to be parse by the driver. */
    void* nothing
)
```

DESCRIPTION This routine initializes the driver and the device to the operational state. All of the device specific parameters are passed in the *initString*.

The string contains the target specific parameters like this:

"unit:register addr:int vector:int level:shmem addr:shmem size:shmem width"

RETURNS An END object pointer or NULL on error.

SEE ALSO *ntEnd*

ntMemInit()

NAME *ntMemInit()* – initialize memory for the chip

SYNOPSIS

```
STATUS ntMemInit
(
    NTEND_DEVICE * pDrvCtrl /* device to be initialized */
)
```

DESCRIPTION This routine is highly specific to the device.

RETURNS OK or ERROR.

SEE ALSO *ntEnd*

ntParse()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>ntParse()</i> – parse the init string |
| SYNOPSIS | <pre> STATUS ntParse (NTEND_DEVICE * pDrvCtrl, char * initString) </pre> |
| DESCRIPTION | <p>Parse the input string. Fill in values in the driver control structure. The initialization string format is:</p> <p>"unit:csrAdr:rapAdr:vecnum:intLvl:memAdrs:memSize:memWidth"</p> <p><i>unit</i> Device unit number, a small integer.</p> <p><i>vecNum</i> Interrupt vector number (used with <i>sysIntConnect()</i>)</p> <p><i>intLvl</i> Interrupt level (isn't really used)</p> |
| RETURNS | OK or ERROR for invalid arguments. |
| SEE ALSO | <i>ntEnd</i> |

ntPassFsDevInit()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>ntPassFsDevInit()</i> – associate a device with ntPassFs file system functions |
| SYNOPSIS | <pre> void *ntPassFsDevInit (char * devName /* device name */) </pre> |
| DESCRIPTION | <p>This routine associates the name <i>devName</i> with the file system and installs it in the I/O System's device table. The driver number used when the device is added to the table is that which was assigned to the ntPassFs library during <i>ntPassFsInit()</i>.</p> |
| RETURNS | A pointer to the volume descriptor, or NULL if there is an error. |
| SEE ALSO | <i>ntPassFsLib</i> |

ntPassFsInit()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>ntPassFsInit()</i> – prepare to use the ntPassFs library |
| SYNOPSIS | <pre>STATUS ntPassFsInit (int nPassfs /* number of ntPass-through file systems */)</pre> |
| DESCRIPTION | <p>This routine initializes the ntPassFs library. It must be called exactly once, before any other routines in the library. The argument specifies the number of ntPassFs devices that may be open at once. This routine installs ntPassFsLib as a driver in the I/O system driver table, allocates and sets up the necessary memory structures, and initializes semaphores.</p> <p>Normally this routine is called from the root task, <i>usrRoot()</i>, in <i>usrConfig()</i>. To enable this initialization, define INCLUDE_PASSFS in configAll.h.</p> |
| NOTE | Maximum number of ntPass-through file systems is 1. |
| RETURNS | OK, or ERROR. |
| SEE ALSO | ntPassFsLib |

ntPollStart()

| | |
|-----------------|--------------------------------------------------------------|
| NAME | <i>ntPollStart()</i> – start polled mode operations |
| SYNOPSIS | <pre>STATUS ntPollstart (NTEND_DEVICE* pDrvCtrl)</pre> |
| RETURNS | OK or ERROR. |
| SEE ALSO | ntEnd |

ntPollStop()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>ntPollStop()</i> – stop polled mode operations |
| SYNOPSIS | <pre> STATUS ntPollStop (NTEND_DEVICE* pDrvCtrl) </pre> |
| DESCRIPTION | <p>This function terminates polled mode operation. The device returns to interrupt mode. The device interrupts are enabled, the current mode flag is switched to indicate interrupt mode and the device is then reconfigured for interrupt operation.</p> |
| RETURNS | OK or ERROR. |
| SEE ALSO | <i>ntEnd</i> |

o0()

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>o0()</i> – return the contents of register o0 (also o1 – o7) (SPARC) |
| SYNOPSIS | <pre> int o0 (int taskId /* task ID, 0 means default task */) </pre> |
| DESCRIPTION | <p>This command extracts the contents of out register o0 from the TCB of a specified task. If <i>taskId</i> is omitted or 0, the current default task is assumed.</p> <p>Similar routines are provided for all out registers (o0 – o7): <i>o0()</i> – <i>o7()</i>.</p> <p>The stack pointer is accessed via o6.</p> |
| RETURNS | The contents of register o0 (or the requested register). |
| SEE ALSO | dbgArchLib , <i>VxWorks Programmer's Guide: Target Shell</i> |

open()

open()**NAME** *open()* – open a file

SYNOPSIS

```
int open
(
    const char * name, /* name of the file to open */
    int         flags, /* O_RDONLY, O_WRONLY, O_RDWR, or O_CREAT */
    int         mode   /* mode of file to create (UNIX chmod style) */
)
```

DESCRIPTION This routine opens a file for reading, writing, or updating, and returns a file descriptor for that file. The arguments to *open()* are the filename and the type of access:

O_RDONLY (0) (or READ) - open for reading only.
O_WRONLY (1) (or WRITE) - open for writing only.
O_RDWR (2) (or UPDATE) - open for reading and writing.
O_CREAT (0x0200) - create a file.

In general, *open()* can only open pre-existing devices and files. However, for NFS network devices only, files can also be created with *open()* by performing a logical OR operation with O_CREAT and the *flags* argument. In this case, the file is created with a UNIX chmod-style file mode, as indicated with *mode*. For example:

```
fd = open ("/usr/myFile", O_CREAT | O_RDWR, 0644);
```

Only the NFS driver uses the *mode* argument.

NOTE For more information about situations when there are no file descriptors available, see the manual entry for *iosInit()*.

RETURNS A file descriptor number, or ERROR if a file name is not specified, the device does not exist, no file descriptors are available, or the driver returns ERROR.

ERRNO ELOOP

SEE ALSO *ioLib*, *creat()*

opendir()

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>opendir()</i> – open a directory for searching (POSIX) |
| SYNOPSIS | <pre>DIR *opendir (char * dirName /* name of directory to open */)</pre> |
| DESCRIPTION | <p>This routine opens the directory named by <i>dirName</i> and allocates a directory descriptor (DIR) for it. A pointer to the DIR structure is returned. The return of a NULL pointer indicates an error.</p> <p>After the directory is opened, <i>readdir()</i> is used to extract individual directory entries. Finally, <i>closedir()</i> is used to close the directory.</p> |
| WARNING | For remote file systems mounted over netDrv , <i>opendir()</i> fails, because the netDrv implementation strategy does not provide a way to distinguish directories from plain files. To permit use of <i>opendir()</i> on remote files, use NFS rather than netDrv. |
| RETURNS | A pointer to a directory descriptor, or NULL if there is an error. |
| SEE ALSO | <i>dirLib</i> , <i>closedir()</i> , <i>readdir()</i> , <i>rewinddir()</i> , <i>ls()</i> |

operator delete()

| | |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>operator delete()</i> – default run-time support for memory deallocation (C++) |
| SYNOPSIS | <pre>extern void operator delete (void * pMem /* pointer to dynamically-allocated object */)</pre> |
| DESCRIPTION | This function provides the default implementation of operator delete. It returns the memory, previously allocated by operator new, to the VxWorks system memory partition. |
| RETURNS | N/A |
| SEE ALSO | <i>cplusplusLib</i> |

operator new()

NAME *operator new()* – default run-time support for operator new (C++)

SYNOPSIS

```
extern void * operator new
(
    size_t n /* size of object to allocate */
) throw (std::bad_alloc)
```

DESCRIPTION This function provides the default implementation of operator new. It allocates memory from the system memory partition for the requested object. The value, when evaluated, is a pointer of the type **pointer-to-*T*** where *T* is the type of the new object.

If allocation fails a new-handler, if one is defined, is called. If the new-handler returns, presumably after attempting to recover from the memory allocation failure, allocation is retried. If there is no new-handler an exception of type "bad_alloc" is thrown.

RETURNS Pointer to new object.

THROWS std::bad_alloc if allocation failed.

SEE ALSO cplusplus

operator new()

NAME *operator new()* – default run-time support for operator new (nothrow) (C++)

SYNOPSIS

```
extern void * operator new
(
    size_t          n, /* size of object to allocate */
    const nothrow_t & /* supply argument of "nothrow" here */
) throw ()
```

DESCRIPTION This function provides the default implementation of operator new (nothrow). It allocates memory from the system memory partition for the requested object. The value, when evaluated, is a pointer of the type **pointer-to-*T*** where *T* is the type of the new object.

If allocation fails, a new-handler, if one is defined, is called. If the new-handler returns, presumably after attempting to recover from the memory allocation failure, allocation is retried. If the new_handler throws a bad_alloc exception, the exception is caught and 0 is returned. If allocation fails and there is no new_handler 0 is returned.

RETURNS Pointer to new object or 0 if allocation fails.

INCLUDE FILES `new`

SEE ALSO `cplusplus`

operator new()

NAME *operator new()* – run-time support for operator new with placement (C++)

SYNOPSIS

```
extern void * operator new
(
    size_t n, /* size of object to allocate (unused) */
    void * pMem /* pointer to allocated memory */
)
```

DESCRIPTION This function provides the default implementation of the global new operator, with support for the placement syntax. New-with-placement is used to initialize objects for which memory has already been allocated. *pMem* points to the previously allocated memory.

RETURNS *pMem*

INCLUDE FILES `new`

SEE ALSO `cplusplus`

ospfExtRouteAdd()

NAME *ospfExtRouteAdd()* – import external route into OSPF domain (OSPF Opt.)

SYNOPSIS

```
STATUS ospfExtRouteAdd
(
    uint32_t destIp, /* destination IP address */
    uint32_t destMask, /* destination mask */
    uint32_t nextHopIp, /* IP address of next hop */
    int cost, /* cost to advertise in domain */
    int extRouteType, /* 1 = external type1, 2 = external type2 */
    int tos /* type of service */
)
```

DESCRIPTION This function is used to import an external route into the OSPF domain. The destination address and mask are *destIp* and *destMask* respectively while *nextHopIp* is the IP address of the next hop. The cost to advertise in the OSPF domain is *cost* and route type is *routeType*, which can have the value 1 or 2 for type 1 and type 2 routes respectively. All IP addresses and masks in this call are in network byte order.

RETURNS OK or ERROR.

SEE ALSO **ospfLib**

ospfExtRouteDelete()

NAME *ospfExtRouteDelete()* – delete external route imported into OSPF (OSPF Opt.)

SYNOPSIS

```
STATUS ospfExtRouteDelete
(
    uint32_t destIp,          /* destination IP address */
    uint32_t destMask,       /* destination mask */
    int      extRouteType,   /* 1 = external type1, 2 = external type2 */
    int      tos             /* type of service */
)
```

DESCRIPTION This function is used to delete an external route imported into the OSPF domain. The destination address and mask are *destIp* and *destMask* respectively. The route type is *extRouteType* which may have the value 1 or 2 for type 1 and type 2 routes, respectively. All IP addresses and masks in this call are in network byte order.

RETURNS OK or ERROR.

SEE ALSO **ospfLib**

ospfInit()

NAME *ospfInit()* – function to initialize OSPF routing (OSPF Opt.)

SYNOPSIS

```
STATUS ospfInit
(
    int      priority, /* task priority */
    int      options,  /* task options */
    int      stackSize, /* task stack size */
)
```

```

int    routerId, /* routerId, host byte order */
FUNCPTR pAuthHook /* ospf authentication hook */
)

```

DESCRIPTION

This function initializes the OSPF facilities. This includes creating OSPF tasks, which are created with a priority of *priority*, options set to *options*, a stack size of *stackSize*, and an OSPF router ID of *routerid*. If *routerId* is 0, the IP address of one of the interfaces is used as the router ID. The *pAuthHook* parameter expects a pointer to a user-provided authentication routine. For every received packet, the authentication function:

```
(*ospfAuthHook) (pIfkey, pPktKey, ipAddr)
```

The *pIfkey* parameter is a pointer to the authorization key associated with the interface. The *pPktKey* parameter is a pointer to the key in the received packet. The *ipAddr* is the IP address in network byte order of the interface on which the packet was received. To set the interface authorization key, call *m2OspfIfEntrySet()*. The *ospfAuthHook()* routine returns TRUE if the packet is acceptable. Otherwise, it returns FALSE.

After this function has returned, you can use the *m2Ospf*Set()* configuration routines to alter the settings.

RETURNS

OK or ERROR.

SEE ALSO

ospfLib

ospfNbmaDstAdd()

NAME

ospfNbmaDstAdd() – add NBMA destination

SYNOPSIS

```

STATUS ospfNbmaDstAdd
(
    uint32_t ipAddress, /* neighbor IP address, network order */
    uint32_t ifIpAddress, /* local interface IP address, network order */
    BOOL    eligible /* TRUE if neighbor is eligible to be DR */
)

```

DESCRIPTION

On a non-broadcast multiple access network, a router capable of becoming designated router must be made aware of the IP addresses of all other routers on the network. The neighbor router is specified by its IP address *ipAddress*, the local interface IP address is *ifIpAddress* and *eligible* specifies if the neighbor is capable of acting as a designated router.

RETURNS

OK or ERROR.

SEE ALSO

ospfLib

ospfNbmaDstDelete()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>ospfNbmaDstDelete()</i> – delete NBMA destination |
| SYNOPSIS | <pre>STATUS ospfNbmaDstDelete (uint32_t ipAddress, /* neighbor IP address, network order */ uint32_t ifIpAddress /* local interface IP address, network order */)</pre> |
| DESCRIPTION | Delete neighbor on a NBMA network, previously created with <i>ospfNbmaDstAdd()</i> . The neighbor is specified by its IP address <i>ipAddress</i> and the local interface IP address is <i>ifIpAddress</i> . |
| RETURNS | OK or ERROR. |
| SEE ALSO | ospfLib |

ospfTerminate()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>ospfTerminate()</i> – free OSPF resources and delete OSPF tasks |
| SYNOPSIS | <pre>void ospfTerminate ()</pre> |
| DESCRIPTION | This function frees all the resources used by OSPF. This includes deleting the two VxWorks tasks used to manage OSPF. You are free to restart OSPF after this function has returned. |
| RETURNS | N/A |
| SEE ALSO | ospfLib |

passFsDevInit()

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>passFsDevInit()</i> – associate a device with passFs file system functions |
| SYNOPSIS | <pre>void *passFsDevInit (char * devName /* device name */)</pre> |
| DESCRIPTION | This routine associates the name <i>devName</i> with the file system and installs it in the I/O System's device table. The driver number used when the device is added to the table is that which was assigned to the passFs library during <i>passFsInit()</i> . |
| RETURNS | A pointer to the volume descriptor, or NULL if there is an error. |
| SEE ALSO | <i>passFsLib</i> |

passFsInit()

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>passFsInit()</i> – prepare to use the passFs library |
| SYNOPSIS | <pre>STATUS passFsInit (int nPassfs /* number of pass-through file systems */)</pre> |
| DESCRIPTION | <p>This routine initializes the passFs library. It must be called exactly once, before any other routines in the library. The argument specifies the number of passFs devices that may be open at once. This routine installs passFsLib as a driver in the I/O system driver table, allocates and sets up the necessary memory structures, and initializes semaphores.</p> <p>Normally this routine is called from the root task, <i>usrRoot()</i>, in <i>usrConfig()</i>. This initialization is enabled when the configuration macro INCLUDE_PASSFS is defined.</p> |
| NOTE | Maximum number of pass-through file systems is 1. |
| RETURNS | OK, or ERROR. |
| SEE ALSO | <i>passFsLib</i> |

pause()

pause()

NAME *pause()* – suspend the task until delivery of a signal (POSIX)

SYNOPSIS `int pause (void)`

DESCRIPTION This routine suspends the task until delivery of a signal.

NOTE Since the *pause()* function suspends thread execution indefinitely, there is no successful completion return value.

RETURNS -1, always.

ERRNO EINTR

SEE ALSO sigLib

pc()

NAME *pc()* – return the contents of the program counter

SYNOPSIS `int pc
(
 int task /* task ID */
)`

DESCRIPTION This command extracts the contents of the program counter for a specified task from the task's TCB. If *task* is omitted or 0, the current task is used.

RETURNS The contents of the program counter.

SEE ALSO `usrLib`, *ti()*, *VxWorks Programmer's Guide: Target Shell*

pccardAtaEnabler()

NAME *pccardAtaEnabler()* – enable the PCMCIA-ATA device

SYNOPSIS

```
STATUS pccardAtaEnabler
(
    int          sock,          /* socket no. */
    ATA_RESOURCE * pAtaResource, /* pointer to ATA resources */
    int          numEnt,       /* number of ATA resource entries */
    FUNCPTR      showRtn      /* ATA show routine */
)
```

DESCRIPTION This routine enables the PCMCIA-ATA device.

RETURNS OK, `ERROR_FIND` if there is no ATA card, or `ERROR` if another error occurs.

SEE ALSO `pccardLib`

pccardEltEnabler()

NAME *pccardEltEnabler()* – enable the PCMCIA Etherlink III card

SYNOPSIS

```
STATUS pccardEltEnabler
(
    int          sock,          /* socket no. */
    ELT_RESOURCE * pEltResource, /* pointer to ELT resources */
    int          numEnt,       /* number of ELT resource entries */
    FUNCPTR      showRtn      /* show routine */
)
```

DESCRIPTION This routine enables the PCMCIA Etherlink III (ELT) card.

RETURNS OK, `ERROR_FIND` if there is no ELT card, or `ERROR` if another error occurs.

SEE ALSO `pccardLib`

pccardMkfs()

pccardMkfs()

NAME *pccardMkfs()* – initialize a device and mount a DOS file system

SYNOPSIS `STATUS pccardMkfs
(
 int sock, /* socket number */
 char * pName /* name of a device */
)`

DESCRIPTION This routine initializes a device and mounts a DOS file system.

RETURNS OK or ERROR.

SEE ALSO *pccardLib*

pccardMount()

NAME *pccardMount()* – mount a DOS file system

SYNOPSIS `STATUS pccardMount
(
 int sock, /* socket number */
 char * pName /* name of a device */
)`

DESCRIPTION This routine mounts a DOS file system.

RETURNS OK or ERROR.

SEE ALSO *pccardLib*

pccardSramEnabler()

NAME *pccardSramEnabler()* – enable the PCMCIA-SRAM driver

SYNOPSIS

```
STATUS pccardSramEnabler
(
    int          sock,          /* socket no. */
    SRAM_RESOURCE * pSramResource, /* pointer to SRAM resources */
    int          numEnt,        /* number of SRAM resource entries */
    FUNCPTR      showRtn        /* SRAM show routine */
)
```

DESCRIPTION This routine enables the PCMCIA-SRAM driver.

RETURNS OK, `ERROR_FIND` if there is no SRAM card, or `ERROR` if another error occurs.

SEE ALSO `pccardLib`

pccardTffsEnabler()

NAME *pccardTffsEnabler()* – enable the PCMCIA-TFFS driver

SYNOPSIS

```
STATUS pccardTffsEnabler
(
    int          sock,          /* socket no. */
    TFFS_RESOURCE * pTffsResource, /* pointer to TFFS resources */
    int          numEnt,        /* number of SRAM resource entries */
    FUNCPTR      showRtn        /* TFFS show routine */
)
```

DESCRIPTION This routine enables the PCMCIA-TFFS driver.

RETURNS OK, `ERROR_FIND` if there is no TFFS(Flash) card, or `ERROR` if another error occurs.

SEE ALSO `pccardLib`

pcicInit()

pcicInit()

NAME *pcicInit()* – initialize the PCIC chip

SYNOPSIS

```
STATUS pcicInit
(
    int    ioBase,    /* IO base address */
    int    intVec,    /* interrupt vector */
    int    intLevel, /* interrupt level */
    FUNCPTR showRtn  /* show routine */
)
```

DESCRIPTION This routine initializes the PCIC chip.

RETURNS OK, or ERROR if the PCIC chip cannot be found.

SEE ALSO *pcic*

pcicShow()

NAME *pcicShow()* – show all configurations of the PCIC chip

SYNOPSIS

```
void pcicShow
(
    int sock /* socket no. */
)
```

DESCRIPTION This routine shows all configurations of the PCIC chip.

RETURNS N/A

SEE ALSO *pcicShow*

pcmciaad()

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>pcmciaad()</i> – handle task-level PCMCIA events |
| SYNOPSIS | <code>void pcmciaad (void)</code> |
| DESCRIPTION | This routine is spawned as a task by <i>pcmciaInit()</i> to perform functions that cannot be performed at interrupt or trap level. It has a priority of 0. Do not suspend, delete, or change the priority of this task. |
| RETURNS | N/A |
| SEE ALSO | <i>pcmciaLib</i> , <i>pcmciaInit()</i> |

pcmciaInit()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>pcmciaInit()</i> – initialize the PCMCIA event-handling package |
| SYNOPSIS | <code>STATUS pcmciaInit (void)</code> |
| DESCRIPTION | This routine installs the PCMCIA event-handling facilities and spawns <i>pcmciaad()</i> , which performs special PCMCIA event-handling functions that need to be done at task level. It also creates the message queue used to communicate with <i>pcmciaad()</i> . |
| RETURNS | OK, or ERROR if a message queue cannot be created or <i>pcmciaad()</i> cannot be spawned. |
| SEE ALSO | <i>pcmciaLib</i> , <i>pcmciaad()</i> |

pcmciaShow()

| | |
|-----------------|------------------------------------------------------------------|
| NAME | <i>pcmciaShow()</i> – show all configurations of the PCMCIA chip |
| SYNOPSIS | <pre>void pcmciaShow (int sock /* socket no. */)</pre> |

DESCRIPTION This routine shows all configurations of the PCMCIA chip.

RETURNS N/A

SEE ALSO **pcmciaShow**

pcmciaShowInit()

NAME *pcmciaShowInit()* – initialize all show routines for PCMCIA drivers

SYNOPSIS `void pcmciaShowInit (void)`

DESCRIPTION This routine initializes all show routines related to PCMCIA drivers.

RETURNS N/A

SEE ALSO **pcmciaShow**

pcw()

NAME *pcw()* – return the contents of the **pcw** register (i960)

SYNOPSIS `int pcw
(
 int taskId /* task ID, 0 means default task */
)`

DESCRIPTION This command extracts the contents of the **pcw** register from the TCB of a specified task. If *taskId* is omitted or 0, the current default task is assumed.

RETURNS The contents of the **pcw** register.

SEE ALSO **dbgArchLib**, *VxWorks Programmer's Guide: Target Shell*

pentiumBtc()

NAME *pentiumBtc()* – execute atomic compare-and-exchange instruction to clear a bit

SYNOPSIS

```
STATUS pentiumBtc
(
)
char * pFlag; /* flag address */
```

DESCRIPTION This routine compares a byte specified by the first parameter with TRUE. If it is TRUE, it changes it to 0 and returns OK. If it is not TRUE, it returns ERROR. LOCK and CMPXCHGB are used to get the atomic memory access.

RETURNS OK or ERROR if the specified flag is not TRUE

SEE ALSO *pentiumALib*

pentiumBts()

NAME *pentiumBts()* – execute atomic compare-and-exchange instruction to set a bit

SYNOPSIS

```
STATUS pentiumBts
(
)
char * pFlag; /* flag address */
```

DESCRIPTION This routine compares a byte specified by the first parameter with 0. If it is 0, it changes it to TRUE and returns OK. If it is not 0, it returns ERROR. LOCK and CMPXCHGB are used to get the atomic memory access.

RETURNS OK or ERROR if the specified flag is not zero

SEE ALSO *pentiumALib*

pentiumCr4Get()

NAME *pentiumCr4Get()* – Get a content of CR4 register

SYNOPSIS `int pentiumCr4Get (void)`

DESCRIPTION This routine gets a content of CR4 register.

RETURNS a content of CR4 register

SEE ALSO `pentiumALib`

pentiumCr4Set()

NAME *pentiumCr4Set()* – Set a specified value to CR4 register

SYNOPSIS `void pentiumCr4Set
 (
)
 int cr4; /* value to write CR4 register */`

DESCRIPTION This routine sets a specified value to CR4 register.

RETURNS N/A

SEE ALSO `pentiumALib`

pentiumMcaShow()

NAME *pentiumMcaShow()* – show MCA (Machine Check Architecture) registers

SYNOPSIS `void pentiumMcaShow (void)`

DESCRIPTION This routine shows Machine-Check global control registers and Error-Reporting register banks. Number of the Error-Reporting register banks is kept in a variable `mcaBanks`. `MCi_ADDR` and `MCi_MISC` registers in the Error-Reporting register bank are showed if `MCi_STATUS` indicates that these registers are valid.

RETURNS N/A
SEE ALSO `pentiumShow`

pentiumMsrGet()

NAME *pentiumMsrGet()* – get a content of the specified MSR (Model Specific Register)

SYNOPSIS

```
void pentiumMsrGet  
(  
    )  
    int addr; /* MSR address */  
    long long int * pData; /* MSR data */
```

DESCRIPTION This routine gets a content of the specified MSR. The first parameter is an address of the MSR. The second parameter is a pointer of 64Bit variable.

RETURNS N/A

SEE ALSO `pentiumALib`

pentiumMsrSet()

NAME *pentiumMsrSet()* – set a value to the specified MSR (Model Specific Registers)

SYNOPSIS

```
void pentiumMsrSet  
(  
    )  
    int addr; /* MSR address */  
    long long int * pData; /* MSR data */
```

DESCRIPTION This routine sets a value to a specified MSR. The first parameter is an address of the MSR. The second parameter is a pointer of 64Bit variable.

RETURNS N/A

SEE ALSO `pentiumALib`

pentiumMtrrDisable()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>pentiumMtrrDisable()</i> – disable MTRR (Memory Type Range Register) |
| SYNOPSIS | <code>void pentiumMtrrDisable (void)</code> |
| DESCRIPTION | This routine disables the MTRR that provide a mechanism for associating the memory types with physical address ranges in system memory. |
| RETURNS | N/A |
| SEE ALSO | <code>pentiumLib</code> |

pentiumMtrrEnable()

| | |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>pentiumMtrrEnable()</i> – enable MTRR (Memory Type Range Register) |
| SYNOPSIS | <code>void pentiumMtrrEnable (void)</code> |
| DESCRIPTION | This routine enables the MTRR that provide a mechanism for associating the memory types with physical address ranges in system memory. |
| RETURNS | N/A |
| SEE ALSO | <code>pentiumLib</code> |

pentiumMtrrGet()

| | |
|-----------------|------------------------------------------------------------------------|
| NAME | <i>pentiumMtrrGet()</i> – get MTRRs to a specified MTRR table |
| SYNOPSIS | <pre>STATUS pentiumMtrrGet (MTRR * pMtrr /* MTRR table */)</pre> |

DESCRIPTION This routine gets MTRRs to a specified MTRR table with RDMSR instruction. The read MTRRs are CAP register, DEFTYPE register, fixed range MTRRs, and variable range MTRRs.

RETURNS OK, or ERROR if MTRR is being accessed.

SEE ALSO *pentiumLib*

pentiumMtrrSet()

NAME *pentiumMtrrSet()* – set MTRRs from specified MTRR table with WRMSR instruction.

SYNOPSIS

```
STATUS pentiumMtrrSet
(
    MTRR * pMtrr /* MTRR table */
)
```

DESCRIPTION This routine sets MTRRs from specified MTRR table with WRMSR instruction. The written MTRRs are DEFTYPE register, fixed range MTRRs, and variable range MTRRs.

RETURNS OK, or ERROR if MTRR is enabled or being accessed.

SEE ALSO *pentiumLib*

pentiumPmcGet()

NAME *pentiumPmcGet()* – get contents of PMC0 and PMC1

SYNOPSIS

```
void pentiumPmcGet
(
    long long int * pPmc0; /* Performance Monitoring Counter 0 */
    long long int * pPmc1; /* Performance Monitoring Counter 1 */
)
```

DESCRIPTION This routine gets contents of both PMC0 (Performance Monitoring Counter 0) and PMC1. The first parameter is a pointer of 64Bit variable to store the content of the Counter 0, and the second parameter is for the Counter 1.

RETURNS N/A

SEE ALSO **pentiumALib**

pentiumPmcGet0()

NAME *pentiumPmcGet0()* – get a content of PMC0

SYNOPSIS

```
void pentiumPmcGet0
(
)
long long int * pPmc0; /* Performance Monitoring Counter 0 */
```

DESCRIPTION This routine gets a content of PMC0 (Performance Monitoring Counter 0). Parameter is a pointer of 64Bit variable to store the content of the Counter.

RETURNS N/A

SEE ALSO **pentiumALib**

pentiumPmcGet1()

NAME *pentiumPmcGet1()* – get a content of PMC1

SYNOPSIS

```
void pentiumPmcGet1
(
)
long long int * pPmc1; /* Performance Monitoring Counter 1 */
```

DESCRIPTION This routine gets a content of PMC1 (Performance Monitoring Counter 1). Parameter is a pointer of 64Bit variable to store the content of the Counter.

RETURNS N/A

SEE ALSO **pentiumALib**

pentiumPmcReset()

NAME *pentiumPmcReset()* – reset both PMC0 and PMC1

SYNOPSIS `void pentiumPmcReset (void)`

DESCRIPTION This routine resets both PMC0 (Performance Monitoring Counter 0) and PMC1.

RETURNS N/A

SEE ALSO *pentiumALib*

pentiumPmcReset0()

NAME *pentiumPmcReset0()* – reset PMC0

SYNOPSIS `void pentiumPmcReset0 (void)`

DESCRIPTION This routine resets PMC0 (Performance Monitoring Counter 0).

RETURNS N/A

SEE ALSO *pentiumALib*

pentiumPmcReset1()

NAME *pentiumPmcReset1()* – reset PMC1

SYNOPSIS `void pentiumPmcReset1 (void)`

DESCRIPTION This routine resets PMC1 (Performance Monitoring Counter 1).

RETURNS N/A

SEE ALSO *pentiumALib*

pentiumPmcShow()

NAME *pentiumPmcShow()* – show PMCs (Performance Monitoring Counters)

SYNOPSIS

```
void pentiumPmcShow
(
    BOOL zap /* 1: reset PMC0 and PMC1 */
)
```

DESCRIPTION This routine shows Performance Monitoring Counter 0 and 1. Monitored events are selected by Performance Event Select Registers in *pentiumPmcStart()*. These counters are cleared to 0 if the parameter "zap" is TRUE.

RETURNS N/A

SEE ALSO *pentiumShow*

pentiumPmcStart()

NAME *pentiumPmcStart()* – start both PMC0 and PMC1

SYNOPSIS

```
STATUS pentiumPmcStart
(
    int pmcEvtSel0; /* Performance Event Select Register 0 */
    int pmcEvtSel1; /* Performance Event Select Register 1 */
)
```

DESCRIPTION This routine starts both PMC0 (Performance Monitoring Counter 0) and PMC1 by writing specified events to Performance Event Select Registers. The first parameter is a content of Performance Event Select Register 0, and the second parameter is for the Performance Event Select Register 1.

RETURNS OK or ERROR if PMC is already started

SEE ALSO *pentiumALib*

pentiumPmcStop()

NAME *pentiumPmcStop()* – stop both PMC0 and PMC1

SYNOPSIS `void pentiumPmcStop (void)`

DESCRIPTION This routine stops both PMC0 (Performance Monitoring Counter 0) and PMC1 by clearing two Performance Event Select Registers.

RETURNS N/A

SEE ALSO *pentiumALib*

pentiumPmcStop1()

NAME *pentiumPmcStop1()* – stop PMC1

SYNOPSIS `void pentiumPmcStop1 (void)`

DESCRIPTION This routine stops only PMC1 (Performance Monitoring Counter 1) by clearing the Performance Event Select Register 1. Note, clearing the Performance Event Select Register 0 stops both counters, PMC0 and PMC1.

RETURNS N/A

SEE ALSO *pentiumALib*

pentiumSerialize()

NAME *pentiumSerialize()* – execute a serializing instruction CPUID

SYNOPSIS `void pentiumSerialize (void)`

DESCRIPTION This routine executes a serializing instruction CPUID. Serialization means that all modifications to flags, registers, and memory by previous instructions are completed before the next instruction is fetched and executed and all buffered writes have drained to memory.

RETURNS N/A

SEE ALSO **pentiumALib**

pentiumTlbFlush()

NAME *pentiumTlbFlush()* – flush TLBs (Translation Lookaside Buffers)

SYNOPSIS `void pentiumTlbFlush (void)`

DESCRIPTION This routine flushes TLBs by loading CR3 register. All of the TLBs are automatically invalidated any time the CR3 register loaded. The page global enable (PGE) flag in register CR4 and the global flag in a page-directory or page-table entry can be used to frequently used pages from being automatically invalidated in the TLBs on a load of CR3 register. The only way to deterministically invalidate global page entries is to clear the PGE flag and then invalidate the TLBs.

RETURNS N/A

SEE ALSO **pentiumALib**

pentiumTscGet32()

NAME *pentiumTscGet32()* – get a lower half of the 64Bit TSC (Timestamp Counter)

SYNOPSIS `UINT32 pentiumTscGet32 (void)`

DESCRIPTION This routine gets a lower half of the 64Bit TSC by RDTSC instruction. RDTSC instruction saves the lower 32Bit in EAX register, so this routine simply returns after executing RDTSC instruction.

RETURNS Lower half of the 64Bit TSC (Timestamp Counter)

SEE ALSO **pentiumALib**

pentiumTscGet64()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>pentiumTscGet64()</i> – get 64Bit TSC (Timestamp Counter) |
| SYNOPSIS | <pre>void pentiumTscGet64 () long long int * pTsc; /* Timestamp Counter */</pre> |
| DESCRIPTION | This routine gets 64Bit TSC by RDTSC instruction. Parameter is a pointer of 64Bit variable to store the content of the Counter. |
| RETURNS | N/A |
| SEE ALSO | <i>pentiumALib</i> |

pentiumTscReset()

| | |
|--------------------|--------------------------------------------------------------------------------|
| NAME | <i>pentiumTscReset()</i> – reset the TSC (Timestamp Counter) |
| SYNOPSIS | <pre>void pentiumTscReset (void)</pre> |
| DESCRIPTION | This routine resets the TSC by writing zero to the TSC with WRMSR instruction. |
| RETURNS | N/A |
| SEE ALSO | <i>pentiumALib</i> |

period()

| | |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>period()</i> – spawn a task to call a function periodically |
| SYNOPSIS | <pre>int period (int secs, /* period in seconds */ FUNCPTR func, /* function to call repeatedly */ int arg1, /* first of eight args to pass to func */</pre> |

periodRun()

```

    int    arg2,
    int    arg3,
    int    arg4,
    int    arg5,
    int    arg6,
    int    arg7,
    int    arg8
)

```

DESCRIPTION This command spawns a task that repeatedly calls a specified function, with up to eight of its arguments, delaying the specified number of seconds between calls.

For example, to have *i()* display task information every 5 seconds, just type:

```
-> period 5, i
```

NOTE The task is spawned using the *sp()* routine. See the description of *sp()* for details about priority, options, stack size, and task ID.

RETURNS A task ID, or ERROR if the task cannot be spawned.

SEE ALSO *usrLib*, *periodRun()*, *sp()*, *VxWorks Programmer's Guide: Target Shell*, *windsh*, *Tornado User's Guide: Shell*

periodRun()

NAME *periodRun()* – call a function periodically

SYNOPSIS

```

void periodRun
(
    int    secs, /* no. of seconds to delay between calls */
    FUNCPTR func, /* function to call repeatedly */
    int    arg1, /* first of eight args to pass to func */
    int    arg2,
    int    arg3,
    int    arg4,
    int    arg5,
    int    arg6,
    int    arg7,
    int    arg8
)

```

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | This command repeatedly calls a specified function, with up to eight of its arguments, delaying the specified number of seconds between calls. Normally, this routine is called only by <i>period()</i> , which spawns it as a task. |
| RETURNS | N/A |
| SEE ALSO | <i>usrLib</i> , <i>period()</i> , <i>VxWorks Programmer's Guide: Target Shell</i> |

perror()

| | |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>perror()</i> – map an error number in errno to an error message (ANSI) |
| SYNOPSIS | <pre>void perror (const char * __s /* error string */)</pre> |
| DESCRIPTION | This routine maps the error number in the integer expression errno to an error message. It writes a sequence of characters to the standard error stream as follows: first (if <i><__s</i> is not a null pointer and the character pointed to by <i><__s</i> is not the null character), the string pointed to by <i><__s</i> followed by a colon (:) and a space; then an appropriate error message string followed by a new-line character. The contents of the error message strings are the same as those returned by <i>strerror()</i> with the argument errno . |
| INCLUDE FILES | stdio.h |
| RETURNS | N/A |
| SEE ALSO | <i>ansiStdio</i> , <i>strerror()</i> |

pfp()

| | |
|-----------------|---------------------------------------------------------------------------|
| NAME | <i>pfp()</i> – return the contents of register pfp (i960) |
| SYNOPSIS | <pre>int pfp (int taskId /* task ID, 0 means default task */)</pre> |

ping()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | This command extracts the contents of register pfp , the previous frame pointer, from the TCB of a specified task. If <i>taskId</i> is omitted or 0, the current default task is assumed. |
| RETURNS | The contents of the pfp register. |
| SEE ALSO | dbgArchLib , <i>VxWorks Programmer's Guide: Target Shell</i> |

ping()

NAME *ping()* – test that a remote host is reachable

SYNOPSIS

```
STATUS ping
(
    char * host,          /* host to ping */
    int   numPackets,    /* number of packets to receive */
    ulong_t options      /* option flags */
)
```

DESCRIPTION This routine tests that a remote host is reachable by sending ICMP echo request packets, and waiting for replies. It may be called from the VxWorks shell as follows:

```
-> ping "remoteSystem", 1, 0
```

where *remoteSystem* is either a host name that has been previously added to the remote host table by a call to *hostAdd()*, or an Internet address in dot notation (for example, "90.0.0.2").

The second parameter, *numPackets*, specifies the number of ICMP packets to receive from the remote host. If *numPackets* is 1, this routine waits for a single echo reply packet, and then prints a short message indicating whether the remote host is reachable. For all other values of *numPackets*, timing and sequence information is printed as echoed packets are received. If *numPackets* is 0, this routine runs continuously.

If no replies are received within a 5-second timeout period, the routine exits. An ERROR status is returned if no echo replies are received from the remote host.

The following flags may be given through the *options* parameter:

PING_OPT_SILENT

Suppress output. This option is useful for applications that use *ping()* programmatically to examine the return status.

PING_OPT_DONTROUTE

Do not route packets past the local network.

| | |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NOTE | The following global variables can be set from the target shell or Windsh to configure the <i>ping()</i> parameters: <i>_pingTxLen</i> Size of the ICMP echo packet (default 64). <i>_pingTxInterval</i> Packet interval in seconds (default 1 second). <i>_pingTxTmo</i> Packet timeout in seconds (default 5 seconds). |
| RETURNS | OK, or ERROR if the remote host is not reachable. |
| ERRNO | EINVAL, S_pingLib_NOT_INITIALIZED, S_pingLib_TIMEOUT |
| SEE ALSO | <i>pingLib</i> |

pingLibInit()

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>pingLibInit()</i> – initialize the <i>ping()</i> utility |
| SYNOPSIS | <code>STATUS pingLibInit (void)</code> |
| DESCRIPTION | This routine allocates resources used by the <i>ping()</i> utility. It must be called before <i>ping()</i> is used. It is called automatically when the configuration macro <code>INCLUDE_PING</code> is defined. |
| RETURNS | OK, or ERROR if the <i>ping()</i> utility could not be initialized. |
| SEE ALSO | <i>pingLib</i> |

pipeDevCreate()

| | |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>pipeDevCreate()</i> – create a pipe device |
| SYNOPSIS | <code>STATUS pipeDevCreate</code> (char * name, /* name of pipe to be created */ int nMessages, /* max. number of messages in pipe */ |

pipeDrv()

```

    int    nBytes    /* size of each message */
)

```

- DESCRIPTION** This routine creates a pipe device. It allocates memory for the necessary structures and initializes the device. The pipe device will have a maximum of *nMessages* messages of up to *nBytes* each in the pipe at once. When the pipe is full, a task attempting to write to the pipe will be suspended until a message has been read. Messages are lost if written to a full pipe at interrupt level.
- RETURNS** OK, or ERROR if the call fails.
- SEE ALSO** **pipeDrv**

pipeDrv()

- NAME** *pipeDrv()* – initialize the pipe driver
- SYNOPSIS** **STATUS pipeDrv (void)**
- DESCRIPTION** This routine initializes and installs the driver. It must be called before any pipes are created. It is called automatically by the root task, *usrRoot()*, in **usrConfig.c** when the configuration macro **INCLUDE_PIPES** is defined.
- RETURNS** OK, or ERROR if the driver installation fails.
- SEE ALSO** **pipeDrv**

pow()

- NAME** *pow()* – compute the value of a number raised to a specified power (ANSI)
- SYNOPSIS**

```

double pow
(
    double x, /* operand */
    double y /* exponent */
)

```
- DESCRIPTION** This routine returns *x* to the power of *y* in double precision (IEEE double, 53 bits).

A domain error occurs if x is negative and y is not an integral value. A domain error occurs if the result cannot be represented when x is zero and y is less than or equal to zero. A range error may occur.

INCLUDE FILES **math.h**

RETURNS The double-precision value of x to the power of y .

Special cases:

| | | |
|---------------------------------------|----|--------------------------|
| (anything) ** 0 | is | 1 |
| (anything) ** 1 | is | itself |
| (anything) ** NaN | is | NaN |
| NaN ** (anything except 0) | is | NaN |
| +(anything > 1) ** +INF | is | +INF |
| +(anything > 1) ** -INF | is | +0 |
| +(anything < 1) ** +INF | is | +0 |
| +(anything < 1) ** -INF | is | +INF |
| +1 ** +-INF | is | NaN, signal INVALID |
| +0 ** +(anything non-0, NaN) | is | +0 |
| -0 ** +(anything non-0, NaN, odd int) | is | +0 |
| +0 ** -(anything non-0, NaN) | is | +INF, signal DIV-BY-ZERO |
| -0 ** -(anything non-0, NaN, odd int) | is | +INF with signal |
| -0 ** (odd integer) | = | -(+0 ** (odd integer)) |
| +INF ** +(anything except 0, NaN) | is | +INF |
| +INF ** -(anything except 0, NaN) | is | +0 |
| -INF ** (odd integer) | = | -(+INF ** (odd integer)) |
| -INF ** (even integer) | = | (+INF ** (even integer)) |
| -INF ** -(any non-integer, NaN) | is | NaN with signal |
| -(x=anything) ** (k=integer) | is | (-1)**k * (x ** k) |
| -(anything except 0) ** (non-integer) | is | NaN with signal |

SEE ALSO **ansiMath, mathALib**

powf()

NAME *powf()* – compute the value of a number raised to a specified power (ANSI)

SYNOPSIS `float powf`
 (
 `float x, /* operand */`

```
float y /* exponent */  
)
```

- DESCRIPTION** This routine returns the value of x to the power of y in single precision.
- INCLUDE FILES** `math.h`
- RETURNS** The single-precision value of x to the power of y .
- SEE ALSO** `mathALib`

ppc403DevInit()

- NAME** *ppc403DevInit()* – initialize the serial port unit
- SYNOPSIS**
- ```
void ppc403DevInit
(
 PPC403_CHAN * pChan
)
```
- DESCRIPTION** The BSP must already have initialized all the device addresses in the `PPC403_CHAN` structure. This routine initializes some `SIO_CHAN` function pointers and then resets the chip in a quiescent state.
- SEE ALSO** `ppc403Sio`

---

## ***ppc403DummyCallback()***

- NAME** *ppc403DummyCallback()* – dummy callback routine
- SYNOPSIS**
- ```
STATUS ppc403DummyCallback (void)
```
- RETURNS** `ERROR` (always).
- SEE ALSO** `ppc403Sio`

ppc403IntEx()

NAME *ppc403IntEx()* – handle error interrupts

SYNOPSIS

```
void ppc403IntEx
(
    PPC403_CHAN * pChan
)
```

DESCRIPTION This routine handles miscellaneous interrupts on the seial communication controller.

RETURNS N/A

SEE ALSO *ppc403Sio*

ppc403IntRd()

NAME *ppc403IntRd()* – handle a receiver interrupt

SYNOPSIS

```
void ppc403IntRd
(
    PPC403_CHAN * pChan
)
```

DESCRIPTION This routine handles read interrupts from the serial communication controller.

RETURNS N/A

SEE ALSO *ppc403Sio*

ppc403IntWr()

ppc403IntWr()

NAME *ppc403IntWr()* – handle a transmitter interrupt

SYNOPSIS

```
void ppc403IntWr
(
    PPC403_CHAN * pChan
)
```

DESCRIPTION This routine handles write interrupts from the serial communication controller.

RETURNS N/A

SEE ALSO *ppc403Sio*

ppc860DevInit()

NAME *ppc860DevInit()* – initialize the SMC

SYNOPSIS

```
void ppc860DevInit
(
    PPC860SMC_CHAN * pChan
)
```

DESCRIPTION This routine is called to initialize the chip to a quiescent state. Note that the **smcNum** field of **PPC860SMC_CHAN** must be either 1 or 2.

SEE ALSO *ppc860Sio*

ppc860Int()

NAME *ppc860Int()* – handle an SMC interrupt

SYNOPSIS

```
void ppc860Int
(
    PPC860SMC_CHAN * pChan
)
```

DESCRIPTION This routine is called to handle SMC interrupts.

SEE ALSO **ppc860Sio**

2

pppDelete()

NAME *pppDelete()* – delete a PPP network interface

SYNOPSIS

```
void pppDelete
(
    int unit /* PPP interface unit number to delete */
)
```

DESCRIPTION This routine deletes the Point-to-Point Protocol (PPP) network interface specified by the unit number *unit*.

A Link Control Protocol (LCP) terminate request packet is sent to notify the peer of the impending PPP link shut-down. The associated serial interface (*tty*) is then detached from the PPP driver, and the PPP interface is deleted from the list of network interfaces. Finally, all resources associated with the PPP link are returned to the VxWorks system.

RETURNS N/A

SEE ALSO **pppLib**

pppHookAdd()

NAME *pppHookAdd()* – add a hook routine on a unit basis

SYNOPSIS

```
STATUS pppHookAdd
(
    int    unit,    /* unit number */
    FUNCPTR hookRtn, /* hook routine */
    int    hookType /* hook type connect/disconnect */
)
```

DESCRIPTION This routine adds a hook to the Point-to-Point Protocol (PPP) channel. The parameters to this routine specify the unit number (*unit*) of the PPP interface, the hook routine (*hookRtn*),

pppHookDelete()

and the type of hook specifying either a connect hook or a disconnect hook (*hookType*). The following hook types can be specified for the *hookType* parameter:

PPP_HOOK_CONNECT

Specify a connect hook.

PPP_HOOK_DISCONNECT

Specify a disconnect hook.

RETURNS OK, or ERROR if the hook cannot be added to the unit.

SEE ALSO *pppHookLib*, *pppHookDelete()*

pppHookDelete()

NAME *pppHookDelete()* – delete a hook routine on a unit basis

SYNOPSIS

```
STATUS pppHookDelete
(
    int unit,      /* unit number */
    int hookType /* hook type connect/disconnect */
)
```

DESCRIPTION This routine deletes a hook added previously to the Point-to-Point Protocol (PPP) channel. The parameters to this routine specify the unit number (*unit*) of the PPP interface and the type of hook specifying either a connect hook or a disconnect hook (*hookType*). The following hook types can be specified for the *hookType* parameter:

PPP_HOOK_CONNECT

Specify a connect hook.

PPP_HOOK_DISCONNECT

Specify a disconnect hook.

RETURNS OK, or ERROR if the hook cannot be deleted for the unit.

SEE ALSO *pppHookLib*, *pppHookAdd()*

pppInfoGet()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>pppInfoGet()</i> – get PPP link status information |
| SYNOPSIS | <pre>STATUS pppInfoGet (int unit, /* PPP interface unit number to examine */ PPP_INFO * pInfo /* PPP_INFO structure to be filled */)</pre> |
| DESCRIPTION | <p>This routine gets status information pertaining to the specified Point-to-Point Protocol (PPP) link, regardless of the link state. State and option information is gathered for the Link Control Protocol (LCP), Internet Protocol Control Protocol (IPCP), Password Authentication Protocol (PAP), and Challenge-Handshake Authentication Protocol (CHAP).</p> <p>The PPP link information is returned through a PPP_INFO structure, which is defined in h/netinet/ppp/pppShow.h.</p> |
| RETURNS | OK, or ERROR if <i>unit</i> is an invalid PPP unit number. |
| SEE ALSO | pppShow , pppLib |

pppInfoShow()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>pppInfoShow()</i> – display PPP link status information |
| SYNOPSIS | <pre>void pppInfoShow (void)</pre> |
| DESCRIPTION | <p>This routine displays status information pertaining to each initialized Point-to-Point Protocol (PPP) link, regardless of the link state. State and option information is gathered for the Link Control Protocol (LCP), Internet Protocol Control Protocol (IPCP), Password Authentication Protocol (PAP), and Challenge-Handshake Authentication Protocol (CHAP).</p> |
| RETURNS | N/A |
| SEE ALSO | pppShow , pppLib |

pppInit()

pppInit()**NAME** *pppInit()* – initialize a PPP network interface

SYNOPSIS

```
int pppInit
(
    int          unit,          /* PPP interface unit number to initialize */
    char *      devname,       /* name of the tty device to be used */
    char *      local_addr,    /* local IP address of the PPP interface */
    char *      remote_addr,   /* remote peer IP address of the PPP link */
    int         baud,          /* baud rate of tty; NULL = default */
    PPP_OPTIONS * pOptions,    /* PPP options structure pointer */
    char *      fOptions       /* PPP options file name */
)
```

DESCRIPTION This routine initializes a Point-to-Point Protocol (PPP) network interface. The parameters to this routine specify the unit number (*unit*) of the PPP interface, the name of the serial interface (*tty*) device (*devname*), the IP addresses of the local and remote ends of the link, the interface baud rate, an optional configuration options structure pointer, and an optional configuration options file name.

IP ADDRESSES The *local_addr* and *remote_addr* parameters specify the IP addresses of the local and remote ends of the PPP link, respectively. If *local_addr* is NULL, the local IP address will be negotiated with the remote peer. If the remote peer does not assign a local IP address, it will default to the address associated with the local target's machine name. If *remote_addr* is NULL, the remote peer's IP address will be obtained from the remote peer. A routing table entry to the remote peer will be automatically added once the PPP link is established.

CONFIGURATION OPTIONS STRUCTURE

The optional parameter *pOptions* specifies configuration options for the PPP link. If NULL, this parameter is ignored, otherwise it is assumed to be a pointer to a PPP_OPTIONS options structure (defined in **h/netinet/ppp/options.h**).

The "flags" member of the PPP_OPTIONS structure is a bit-mask, where the following bit-flags may be specified:

OPT_NO_ALL

Do not request/allow any options.

OPT_PASSIVE_MODE

Set passive mode.

OPT_SILENT_MODE

Set silent mode.

- OPT_DEFAULTROUTE**
Add default route.
- OPT_PROXYARP**
Add proxy ARP entry.
- OPT_IPCP_ACCEPT_LOCAL**
Accept peer's idea of the local IP address.
- OPT_IPCP_ACCEPT_REMOTE**
Accept peer's idea of the remote IP address.
- OPT_NO_IP**
Disable IP address negotiation.
- OPT_NO_ACC**
Disable address/control compression.
- OPT_NO_PC**
Disable protocol field compression.
- OPT_NO_VJ**
Disable VJ (Van Jacobson) compression.
- OPT_NO_VJCCOMP**
Disable VJ (Van Jacobson) connection ID compression.
- OPT_NO_ASYNCMAP**
Disable async map negotiation.
- OPT_NO_MN**
Disable magic number negotiation.
- OPT_NO_MRU**
Disable MRU (Maximum Receive Unit) negotiation.
- OPT_NO_PAP**
Do not allow PAP authentication with peer.
- OPT_NO_CHAP**
Do not allow CHAP authentication with peer.
- OPT_REQUIRE_PAP**
Require PAP authentication with peer.
- OPT_REQUIRE_CHAP**
Require CHAP authentication with peer.
- OPT_LOGIN**
Use the login password database for PAP authentication of peer.
- OPT_DEBUG**
Enable PPP daemon debug mode.
- OPT_DRIVER_DEBUG**
Enable PPP driver debug mode.

pppInit()

The remaining members of the **PPP_OPTIONS** structure specify PPP configurations options that require string values. These options are:

char *asyncmap

Set the desired async map to the specified string.

char *escape_chars

Set the chars to escape on transmission to the specified string.

char *vj_max_slots

Set maximum number of VJ compression header slots to the specified string.

char *netmask

Set netmask value for negotiation to the specified string.

char *mru

Set MRU value for negotiation to the specified string.

char *mtu

Set MTU (Maximum Transmission Unit) value for negotiation to the specified string.

char *lcp_echo_failure

Set the maximum number of consecutive LCP echo failures to the specified string.

char *lcp_echo_interval

Set the interval in seconds between LCP echo requests to the specified string.

char *lcp_restart

Set the timeout in seconds for the LCP negotiation to the specified string.

char *lcp_max_terminate

Set the maximum number of transmissions for LCP termination requests to the specified string.

char *lcp_max_configure

Set the maximum number of transmissions for LCP configuration requests to the specified string.

char *lcp_max_failure

Set the maximum number of LCP configuration NAKs to the specified string.

char *ipcp_restart

Set the timeout in seconds for IPCP negotiation to the specified string.

char *ipcp_max_terminate

Set the maximum number of transmissions for IPCP termination requests to the specified string.

char *ipcp_max_configure

Set the maximum number of transmissions for IPCP configuration requests to the specified string.

- char *ipcp_max_failure**
Set the maximum number of IPCP configuration NAKs to the specified string.
- char *local_auth_name**
Set the local name for authentication to the specified string.
- char *remote_auth_name**
Set the remote name for authentication to the specified string.
- char *pap_file**
Get PAP secrets from the specified file. This option is necessary if either peer requires PAP authentication.
- char *pap_user_name**
Set the user name for PAP authentication with the peer to the specified string.
- char *pap_passwd**
Set the password for PAP authentication with the peer to the specified string.
- char *pap_restart**
Set the timeout in seconds for PAP negotiation to the specified string.
- char *pap_max_authreq**
Set the maximum number of transmissions for PAP authentication requests to the specified string.
- char *chap_file**
Get CHAP secrets from the specified file. This option is necessary if either peer requires CHAP authentication.
- char *chap_restart**
Set the timeout in seconds for CHAP negotiation to the specified string.
- char *chap_interval**
Set the interval in seconds for CHAP rechallenge to the specified string.
- char *chap_max_challenge**
Set the maximum number of transmissions for CHAP challenge to the specified string.

CONFIGURATION OPTIONS FILE

The optional parameter *fOptions* specifies configuration options for the PPP link. If NULL, this parameter is ignored, otherwise it is assumed to be the name of a configuration options file. The format of the options file is one option per line; comment lines start with "#". The following options are recognized:

- no_all**
Do not request/allow any options.
- passive_mode**
Set passive mode.

pppInit()

silent_mode

Set silent mode.

defaultroute

Add default route.

proxyarp

Add proxy ARP entry.

ipcp_accept_local

Accept peer's idea of the local IP address.

ipcp_accept_remote

Accept peer's idea of the remote IP address.

no_ip

Disable IP address negotiation.

no_acc

Disable address/control compression.

no_pc

Disable protocol field compression.

no_vj

Disable VJ (Van Jacobson) compression.

no_vjcomp

Disable VJ (Van Jacobson) connection ID compression.

no_asyncmap

Disable async map negotiation.

no_mn

Disable magic number negotiation.

no_mru

Disable MRU (Maximum Receive Unit) negotiation.

no_pap

Do not allow PAP authentication with peer.

no_chap

Do not allow CHAP authentication with peer.

require_pap

Require PAP authentication with peer.

require_chap

Require CHAP authentication with peer.

login

Use the login password database for PAP authentication of peer.

debug

Enable PPP daemon debug mode.

driver_debug

Enable PPP driver debug mode.

asynctest value

Set the desired async map to the specified value.

escape_chars value

Set the chars to escape on transmission to the specified value.

vj_max_slots value

Set maximum number of VJ compression header slots to the specified value.

netmask value

Set netmask value for negotiation to the specified value.

mru value

Set MRU value for negotiation to the specified value.

mtu value

Set MTU value for negotiation to the specified value.

lcp_echo_failure value

Set the maximum consecutive LCP echo failures to the specified value.

lcp_echo_interval value

Set the interval in seconds between LCP echo requests to the specified value.

lcp_restart value

Set the timeout in seconds for the LCP negotiation to the specified value.

lcp_max_terminate value

Set the maximum number of transmissions for LCP termination requests to the specified value.

lcp_max_configure value

Set the maximum number of transmissions for LCP configuration requests to the specified value.

lcp_max_failure value

Set the maximum number of LCP configuration NAKs to the specified value.

ipcp_restart value

Set the timeout in seconds for IPCP negotiation to the specified value.

ipcp_max_terminate value

Set the maximum number of transmissions for IPCP termination requests to the specified value.

ipcp_max_configure value

Set the maximum number of transmissions for IPCP configuration requests to the

pppInit()

specified value.

ipcp_max_failure *value*

Set the maximum number of IPCP configuration NAKs to the specified value.

local_auth_name *name*

Set the local name for authentication to the specified name.

remote_auth_name *name*

Set the remote name for authentication to the specified name.

pap_file *file*

Get PAP secrets from the specified file. This option is necessary if either peer requires PAP authentication.

pap_user_name *name*

Set the user name for PAP authentication with the peer to the specified name.

-

Set the password for PAP authentication with the peer to the specified password.

pap_restart *value*

Set the timeout in seconds for PAP negotiation to the specified value.

pap_max_authreq *value*

Set the maximum number of transmissions for PAP authentication requests to the specified value.

chap_file *file*

Get CHAP secrets from the specified file. This option is necessary if either peer requires CHAP authentication.

chap_restart *value*

Set the timeout in seconds for CHAP negotiation to the specified value.

chap_interval *value*

Set the interval in seconds for CHAP rechallenge to the specified value.

chap_max_challenge *value*

Set the maximum number of transmissions for CHAP challenge to the specified value.

AUTHENTICATION The VxWorks PPP implementation supports two separate user authentication protocols: the Password Authentication Protocol (PAP) and the Challenge-Handshake Authentication Protocol (CHAP). If authentication is required by either peer, it must be satisfactorily completed before the PPP link becomes fully operational. If authentication fails, the link will be automatically terminated.

EXAMPLES The following routine initializes a PPP interface that uses the target's second serial port (*/tyCo/1*). The local IP address is 90.0.0.1; the IP address of the remote peer is 90.0.0.10.

The baud rate is the default rate for the *tty* device. VJ compression and authentication have been disabled, and LCP echo requests have been enabled.

```
PPP_OPTIONS pppOpt; /* PPP configuration options */
void routine ()
{
    pppOpt.flags = OPT_PASSIVE_MODE | OPT_NO_PAP | OPT_NO_CHAP | OPT_NO_VJ;
    pppOpt.lcp_echo_interval = "30";
    pppOpt.lcp_echo_failure = "10";
    pppInit (0, "/tyCo/1", "90.0.0.1", "90.0.0.10", 0, &pppOpt, NULL);
}
```

The following routine generates the same results as the previous example. The difference is that the configuration options are obtained from a file rather than a structure.

```
pppFile = "phobos:/tmp/ppp_options"; /* PPP configuration options file */
void routine ()
{
    pppInit (0, "/tyCo/1", "90.0.0.1", "90.0.0.10", 0, NULL, pppFile);
}
```

where phobos:/tmp/ppp_options contains:

```
passive
no_pap
no_chap
no_vj
lcp_echo_interval 30
lcp_echo_failure 10
```

RETURNS OK, or ERROR if the PPP interface cannot be initialized because the daemon task cannot be spawned or memory is insufficient.

SEE ALSO *ppplib*, *pppShow*, *pppDelete()*, *VxWorks Programmer's Guide: Network*

pppSecretAdd()

NAME *pppSecretAdd()* – add a secret to the PPP authentication secrets table

SYNOPSIS

```
STATUS pppSecretAdd
(
    char * client, /* client being authenticated */
    char * server, /* server performing authentication */
    char * secret, /* secret used for authentication */
```

```
char * addr  /* acceptable client IP addresses */  
)
```

DESCRIPTION This routine adds a secret to the Point-to-Point Protocol (PPP) authentication secrets table. This table may be used by the Password Authentication Protocol (PAP) and Challenge-Handshake Authentication Protocol (CHAP) user authentication protocols.

When a PPP link is established, a "server" may require a "client" to authenticate itself using a "secret". Clients and servers obtain authentication secrets by searching secrets files, or by searching the secrets table constructed by this routine. Clients and servers search the secrets table by matching client and server names with table entries, and retrieving the associated secret.

Client and server names in the table consisting of "*" are considered wildcards; they serve as matches for any client and/or server name if an exact match cannot be found.

If *secret* starts with "@", *secret* is assumed to be the name of a file, wherein the actual secret can be read.

If *addr* is not NULL, it should contain a list of acceptable client IP addresses. When a server is authenticating a client and the client's IP address is not contained in the list of acceptable addresses, the link is terminated. Any IP address will be considered acceptable if *addr* is NULL. If this parameter is "-", all IP addresses are disallowed.

RETURNS OK, or ERROR if the secret cannot be added to the table.

SEE ALSO `pppSecretLib`, `pppSecretDelete()`, `pppSecretShow()`

pppSecretDelete()

NAME `pppSecretDelete()` – delete a secret from the PPP authentication secrets table

SYNOPSIS

```
STATUS pppSecretDelete  
(  
    char * client, /* client being authenticated */  
    char * server, /* server performing authentication */  
    char * secret /* secret used for authentication */  
)
```

DESCRIPTION This routine deletes a secret from the Point-to-Point Protocol (PPP) authentication secrets table. When searching for a secret to delete from the table, the wildcard substitution (using "*") is not performed for client and/or server names. The *client*, *server*, and *secret* strings must match the table entry exactly in order to be deleted.

RETURNS OK, or ERROR if the table entry being deleted is not found.

SEE ALSO `pppSecretLib`, `pppSecretAdd()`, `pppSecretShow()`

pppSecretShow()

NAME `pppSecretShow()` – display the PPP authentication secrets table

SYNOPSIS `void pppSecretShow (void)`

DESCRIPTION This routine displays the Point-to-Point Protocol (PPP) authentication secrets table. The information in the secrets table may be used by the Password Authentication Protocol (PAP) and Challenge-Handshake Authentication Protocol (CHAP) user authentication protocols.

RETURNS N/A

SEE ALSO `pppShow`, `pppLib`, `pppSecretAdd()`, `pppSecretDelete()`

pppstatGet()

NAME `pppstatGet()` – get PPP link statistics

SYNOPSIS `STATUS pppstatGet`
`(`
`int unit, /* PPP interface unit number to examine */`
`PPP_STAT * pStat /* PPP_STAT structure to be filled */`
`)`

DESCRIPTION This routine gets statistics for the specified Point-to-Point Protocol (PPP) link. Detailed are the numbers of bytes and packets received and sent through the PPP interface.

The PPP link statistics are returned through a `PPP_STAT` structure, which is defined in `h/netinet/ppp/pppShow.h`.

RETURNS OK, or ERROR if `unit` is an invalid PPP unit number.

SEE ALSO `pppShow`, `pppLib`

pppstatShow()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>pppstatShow()</i> – display PPP link statistics |
| SYNOPSIS | <code>void pppstatShow (void)</code> |
| DESCRIPTION | This routine displays statistics for each initialized Point-to-Point Protocol (PPP) link. Detailed are the numbers of bytes and packets received and sent through each PPP interface. |
| RETURNS | N/A |
| SEE ALSO | <i>pppShow</i> , <i>pppLib</i> |

printErr()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>printErr()</i> – write a formatted string to the standard error stream |
| SYNOPSIS | <pre>int printErr (const char * fmt /* format string to write */)</pre> |
| DESCRIPTION | This routine writes a formatted string to standard error. Its function and syntax are otherwise identical to <i>printf()</i> . |
| RETURNS | The number of characters output, or ERROR if there is an error during output. |
| SEE ALSO | <i>fioLib</i> , <i>printf()</i> |

printErrno()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>printErrno()</i> – print the definition of a specified error status value |
| SYNOPSIS | <pre>void printErrno (int errNo /* status code whose name is to be printed */)</pre> |
| DESCRIPTION | <p>This command displays the error-status string, corresponding to a specified error-status value. It is only useful if the error-status symbol table has been built and included in the system. If <i>errNo</i> is zero, then the current task status is used by calling <i>errnoGet()</i>.</p> <p>This facility is described in errnoLib.</p> |
| RETURNS | N/A |
| SEE ALSO | usrLib , errnoLib , <i>errnoGet()</i> , <i>VxWorks Programmer's Guide: Target Shell</i> , windsh , <i>Tornado User's Guide: Shell</i> |

printf()

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>printf()</i> – write a formatted string to the standard output stream (ANSI) |
| SYNOPSIS | <pre>int printf (const char * fmt /* format string to write */)</pre> |
| DESCRIPTION | <p>This routine writes output to standard output under control of the string <i>fmt</i>. The string <i>fmt</i> contains ordinary characters, which are written unchanged, plus conversion specifications, which cause the arguments that follow <i>fmt</i> to be converted and printed as part of the formatted string.</p> <p>The number of arguments for the format is arbitrary, but they must correspond to the conversion specifications in <i>fmt</i>. If there are insufficient arguments, the behavior is undefined. If the format is exhausted while arguments remain, the excess arguments are evaluated but otherwise ignored. The routine returns when the end of the format string is encountered.</p> <p>The format is a multibyte character sequence, beginning and ending in its initial shift state. The format is composed of zero or more directives: ordinary multibyte characters</p> |

printf()

(not %) that are copied unchanged to the output stream; and conversion specification, each of which results in fetching zero or more subsequent arguments. Each conversion specification is introduced by the % character. After the %, the following appear in sequence:

- Zero or more flags (in any order) that modify the meaning of the conversion specification.
- An optional minimum field width. If the converted value has fewer characters than the field width, it will be padded with spaces (by default) on the left (or right, if the left adjustment flag, described later, has been given) to the field width. The field width takes the form of an asterisk (*) (described later) or a decimal integer.
- An optional precision that gives the minimum number of digits to appear for the **d**, **i**, **o**, **u**, **x**, and **X** conversions, the number of digits to appear after the decimal-point character for **e**, **E**, and **f** conversions, the maximum number of significant digits for the **g** and **G** conversions, or the maximum number of characters to be written from a string in the **s** conversion. The precision takes the form of a period (.) followed either by an asterisk (*) (described later) or by an optional decimal integer; if only the period is specified, the precision is taken as zero. If a precision appears with any other conversion specifier, the behavior is undefined.
- An optional **h** specifying that a following **d**, **i**, **o**, **u**, **x**, and **X** conversion specifier applies to a **short int** or **unsigned short int** argument (the argument will have been promoted according to the integral promotions, and its value converted to **short int** or **unsigned short int** before printing); an optional **h** specifying that a following **n** conversion specifier applies to a pointer to a **short int** argument; an optional **l** (el) specifying that a following **d**, **i**, **o**, **u**, **x**, and **X** conversion specifier applies to a **long int** or **unsigned long int** argument; or an optional **L** specifying that a following **n** conversion specifier applies to a pointer to a **long int** argument. If an **h** or **L** appears with any other conversion specifier, the behavior is undefined.
- WARNING: ANSI C also specifies an optional **L** in some of the same contexts as **l** above, corresponding to a **long double** argument. However, the current release of the VxWorks libraries does not support **long double** data; using the optional **L** gives unpredictable results.
- A character that specifies the type of conversion to be applied.

As noted above, a field width, or precision, or both, can be indicated by an asterisk (*). In this case, an **int** argument supplies the field width or precision. The arguments specifying field width, or precision, or both, should appear (in that order) before the argument (if any) to be converted. A negative field width argument is taken as a - flag followed by a positive field width. A negative precision argument is taken as if the precision were omitted.

The flag characters and their meanings are:

-

The result of the conversion will be left-justified within the field. (it will be

right-justified if this flag is not specified.)

+

The result of a signed conversion will always begin with a plus or minus sign. (It will begin with a sign only when a negative value is converted if this flag is not specified.)

space

If the first character of a signed conversion is not a sign, or if a signed conversion results in no characters, a space will be prefixed to the result. If the **space** and **+** flags both appear, the **space** flag will be ignored.

#

The result is to be converted to an "alternate form." For **o** conversion it increases the precision to force the first digit of the result to be a zero. For **x** (or **X**) conversion, a non-zero result will have "0x" (or "0X") prefixed to it. For **e**, **E**, **f**, **g**, and **G** conversions, the result will always contain a decimal-point character, even if no digits follow it. (Normally, a decimal-point character appears in the result of these conversions only if no digit follows it). For **g** and **G** conversions, trailing zeros will not be removed from the result. For other conversions, the behavior is undefined.

0

For **d**, **i**, **o**, **u**, **x**, **X**, **e**, **E**, **f**, **g**, and **G** conversions, leading zeros (following any indication of sign or base) are used to pad to the field width; no space padding is performed. If the **0** and **-** flags both appear, the **0** flag will be ignored. For **d**, **i**, **o**, **u**, **x**, and **X** conversions, if a precision is specified, the **0** flag will be ignored. For other conversions, the behavior is undefined.

The conversion specifiers and their meanings are:

d, i

The **int** argument is converted to signed decimal in the style **[-]dddd**. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting a zero value with a precision of zero is no characters.

o, u, x, X

The **unsigned int** argument is converted to unsigned octal (**o**), unsigned decimal (**u**), or unsigned hexadecimal notation (**x** or **X**) in the style **dddd**; the letters abcdef are used for **x** conversion and the letters ABCDEF for **X** conversion. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting a zero value with a precision of zero is no characters.

f

The **double** argument is converted to decimal notation in the style **[-]ddd.ddd**, where the number of digits after the decimal point character is equal to the precision specification. If the precision is missing, it is taken as 6; if the precision is zero and

printf()

the # flag is not specified, no decimal-point character appears. If a decimal-point character appears, at least one digit appears before it. The value is rounded to the appropriate number of digits.

e, E

The **double** argument is converted in the style [-]d.ddde+/-dd, where there is one digit before the decimal-point character (which is non-zero if the argument is non-zero) and the number of digits after it is equal to the precision; if the precision is missing, it is taken as 6; if the precision is zero and the # flag is not specified, no decimal-point character appears. The value is rounded to the appropriate number of digits. The E conversion specifier will produce a number with E instead of e, introducing the exponent. The exponent always contains at least two digits. If the value is zero, the exponent is zero.

g, G

The **double** argument is converted in style f or e (or in style E in the case of a G conversion specifier), with the precision specifying the number of significant digits. If the precision is zero, it is taken as 1. The style used depends on the value converted; style e (or E) will be used only if the exponent resulting from such a conversion is less than -4 or greater than or equal to the precision. Trailing zeros are removed from the fractional portion of the result; a decimal-point character appears only if it is followed by a digit.

c

The **int** argument is converted to an **unsigned char**, and the resulting character is written.

s

The argument should be a pointer to an array of character type. Characters from the array are written up to (but not including) a terminating null character; if the precision is specified, no more than that many characters are written. If the precision is not specified or is greater than the size of the array, the array will contain a null character.

p

The argument should be a pointer to **void**. The value of the pointer is converted to a sequence of printable characters, in hexadecimal representation (prefixed with "0x").

n

The argument should be a pointer to an integer into which the number of characters written to the output stream so far by this call to *fprintf()* is written. No argument is converted.

%

A % is written. No argument is converted. The complete conversion specification is %%.

If a conversion specification is invalid, the behavior is undefined.

If any argument is, or points to, a union or an aggregate (except for an array of character type using **s** conversion, or a pointer using **p** conversion), the behavior is undefined.

In no case does a non-existent or small field width cause truncation of a field if the result of a conversion is wider than the field width, the field is expanded to contain the conversion result.

- INCLUDE FILES** **fiolib.h**
- RETURNS** The number of characters written, or a negative value if an output error occurs.
- SEE ALSO** **fiolib**, **fprintf()**, *American National Standard for Information Systems – Programming Language – C, ANSI X3.159-1989: Input/Output (**stdio.h**)*

printLogo()

- NAME** *printLogo()* – print the VxWorks logo
- SYNOPSIS** `void printLogo (void)`
- DESCRIPTION** This command displays the VxWorks banner seen at boot time. It also displays the VxWorks version number and kernel version number.
- RETURNS** N/A
- SEE ALSO** **usrLib**, *VxWorks Programmer's Guide: Target Shell*, **windsh**, *Tornado User's Guide: Shell*

proxyArpLibInit()

- NAME** *proxyArpLibInit()* – initialize proxy ARP
- SYNOPSIS** `STATUS proxyArpLibInit`
 (
 int clientSizeLog2, /* client table size as power of two */
 int portSizeLog2 /* port table size as power of two */
)
- DESCRIPTION** This routine initializes the proxy ARP library by initializing tables and structures and adding the hooks to process ARP, proxy messages, and broadcasts. *clientSizeLog2*

proxyNetCreate()

specifies the client hash table size as a power of two. *portSizeLog2* specifies the port hash table as a power of two. If either of these parameters is zero, a default value will be used. By default, *proxyArpLibInit()* enables broadcast forwarding of the BOOTP server port.

This routine should be called only once; subsequent calls have no effect.

RETURNS OK, or ERROR if unsuccessful.

SEE ALSO *proxyArpLib*

proxyNetCreate()

NAME *proxyNetCreate()* – create a proxy ARP network

SYNOPSIS

```
STATUS proxyNetCreate
(
    char * proxyAddr, /* proxy network address */
    char * mainAddr  /* main network address */
)
```

DESCRIPTION This routine creates a proxy network with the interface *proxyAddr* as the proxy network and the interface *mainAddr* as the main network. The interfaces and the routing tables must be set up correctly, prior to calling this routine. That is, the interfaces must be attached, addresses must be set, and there should be a network route to *mainAddr* and no routes to *proxyAddr*.

proxyAddr and *mainAddr* must reside in the same network address space.

RETURNS OK, or ERROR if unsuccessful.

ERRNO S_proxyArpLib_INVALID_INTERFACE
S_proxyArpLib_INVALID_ADDRESS

SEE ALSO *proxyArpLib*

proxyNetDelete()

NAME *proxyNetDelete()* – delete a proxy network

SYNOPSIS `STATUS proxyNetDelete`
`(`
`char * proxyAddr /* proxy net address */`
`)`

DESCRIPTION This routine deletes the proxy network specified by *proxyAddr*. It also removes all the proxy clients that exist on that network.

RETURNS OK, or ERROR if unsuccessful.

SEE ALSO **proxyArpLib**

proxyNetShow()

NAME *proxyNetShow()* – show proxy ARP networks

SYNOPSIS `void proxyNetShow (void)`

DESCRIPTION This routine displays the proxy networks and their associated clients.

EXAMPLE `-> proxyNetShow`
`main interface 147.11.1.182 proxy interface 147.11.1.183`
`client 147.11.1.184`

RETURNS N/A

proxyPortFwdOff()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>proxyPortFwdOff()</i> – disable broadcast forwarding for a particular port |
| SYNOPSIS | <pre>STATUS proxyPortFwdOff (int port /* port number */)</pre> |
| DESCRIPTION | This routine disables broadcast forwarding on port number <i>port</i> . To disable the (previously enabled) forwarding of all ports via <i>proxyPortFwdOn()</i> , specify zero for <i>port</i> . |
| RETURNS | OK, or ERROR if unsuccessful. |
| SEE ALSO | <i>proxyArpLib</i> |

proxyPortFwdOn()

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>proxyPortFwdOn()</i> – enable broadcast forwarding for a particular port |
| SYNOPSIS | <pre>STATUS proxyPortFwdOn (int port /* port number */)</pre> |
| DESCRIPTION | This routine enables broadcasts destined for the port, <i>port</i> , to be forwarded to and from the proxy network. To enable all ports, specify zero for <i>port</i> . |
| RETURNS | OK, or ERROR if unsuccessful. |
| SEE ALSO | <i>proxyArpLib</i> |

proxyPortShow()

| | |
|-----------------|---------------------------------------------|
| NAME | <i>proxyPortShow()</i> – show enabled ports |
| SYNOPSIS | <pre>void proxyPortShow (void)</pre> |

| | |
|--------------------|-------------------------------------------------------|
| DESCRIPTION | This routine displays the ports currently enabled. |
| EXAMPLE | <pre>-> proxyPortShow enabled ports: port 67</pre> |
| RETURNS | N/A |
| SEE ALSO | proxyArpLib |

proxyReg()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------|
| NAME | <i>proxyReg()</i> – register a proxy client |
| SYNOPSIS | <pre>STATUS proxyReg (char * ifName, /* interface name */ char * proxyAddr /* proxy address */)</pre> |
| DESCRIPTION | This routine sends a message over the network interface <i>ifName</i> to register <i>proxyAddr</i> as a proxy client. |
| RETURNS | OK, or ERROR if unsuccessful. |
| SEE ALSO | proxyLib |

proxyUnreg()

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>proxyUnreg()</i> – unregister a proxy client |
| SYNOPSIS | <pre>STATUS proxyUnreg (char * ifName, /* interface name */ char * proxyAddr /* proxy address */)</pre> |
| DESCRIPTION | This routine sends a message over the network interface <i>ifName</i> to unregister <i>proxyAddr</i> as a proxy client. |

psr()

RETURNS OK, or ERROR if unsuccessful.

SEE ALSO **proxyLib**

psr()

NAME *psr()* – return the contents of the processor status register (SPARC)

SYNOPSIS

```
int psr
(
    int taskId /* task ID, 0 means default task */
)
```

DESCRIPTION This command extracts the contents of the processor status register from the TCB of a specified task. If *taskId* is omitted or 0, the default task is assumed.

RETURNS The contents of the processor status register.

SEE ALSO **dbgArchLib**, **psrShow()**, *VxWorks Programmer's Guide: Target Shell*

psrShow()

NAME *psrShow()* – display the meaning of a specified **psr** value, symbolically (SPARC)

SYNOPSIS

```
void psrShow
(
    ULONG psrValue /* psr value to show */
)
```

DESCRIPTION This routine displays the meaning of all the fields in a specified **psr** value, symbolically. Extracted from **psl.h**:

Definition of bits in the Sun-4 PSR (Processor Status Register)

```
-----
| IMPL | VER |      ICC      | resvd | EC | EF | PIL | S | PS | ET | CWP |
|      |     | N | Z | V | C |      |   |   |   |   |   |   |
|-----|-----|---|---|---|-----|-----|-----|-----|-----|-----|
| 31  28  27  24  23  22  21  20  19  14  13  12  11  8  7  6  5  4  0
```

For compatibility with future revisions, reserved bits are defined to be initialized to zero and, if written, must be preserved.

EXAMPLE

```
-> psrShow 0x00001FE7
Implementation 0, mask version 0:
Fujitsu MB86900 or LSI L64801, 7 windows
    no SWAP, FSQRT, CP, extended fp instructions
Condition codes: . . . .
Coprocessor enables: . EF
Processor interrupt level: f
Flags: S PS ET
Current window pointer: 0x07
->
```

RETURNS N/A

SEE ALSO **dbgArchLib**, *psr()*, *SPARC Architecture Manual*

psrShow()

NAME *psrShow()* – display the meaning of a specified PSR value, symbolically (ARM)

SYNOPSIS

```
STATUS psrShow
(
    UINT32 psrval /* psr value to show */
)
```

DESCRIPTION This routine displays the meaning of all fields in a specified PSR value, symbolically.

RETURNS OK, always.

SEE ALSO **dbgArchLib**

ptyDevCreate()

NAME *ptyDevCreate()* – create a pseudo terminal

SYNOPSIS

```
STATUS ptyDevCreate
(
    char * name,      /* name of pseudo terminal */
    int   rdBufSize, /* size of terminal read buffer */
    int   wrtBufSize /* size of write buffer */
)
```

DESCRIPTION This routine creates a master and slave device which can then be opened by the master and slave processes. The master process simulates the "hardware" side of the driver, while the slave process is the application program that normally talks to a tty driver. Data written to the master device can then be read on the slave device, and vice versa.

RETURNS OK, or ERROR if memory is insufficient.

SEE ALSO *ptyDrv*

ptyDrv()

NAME *ptyDrv()* – initialize the pseudo-terminal driver

SYNOPSIS STATUS *ptyDrv* (void)

DESCRIPTION This routine initializes the pseudo-terminal driver. It must be called before any other routine in this module.

RETURNS OK, or ERROR if the master or slave devices cannot be installed.

SEE ALSO *ptyDrv*

putc()

NAME *putc()* – write a character to a stream (ANSI)

SYNOPSIS

```
int putc
(
    int    c, /* character to write */
    FILE * fp /* stream to write to */
)
```

DESCRIPTION This routine writes a character *c* to a specified stream, at the position indicated by the stream's file position indicator (if defined), and advances the indicator appropriately. This routine is equivalent to *fputc()*, except that if it is implemented as a macro, it may evaluate *fp* more than once; thus, the argument should never be an expression with side effects.

INCLUDE FILES `stdio.h`

RETURNS The character written, or EOF if a write error occurs, with the error indicator set for the stream.

SEE ALSO `ansiStdio`, *fputc()*

putchar()

NAME *putchar()* – write a character to the standard output stream (ANSI)

SYNOPSIS

```
int putchar
(
    int c /* character to write */
)
```

DESCRIPTION This routine writes a character *c* to the standard output stream, at the position indicated by the stream's file position indicator (if defined), and advances the indicator appropriately.

This routine is equivalent to *putc()* with a second argument of `stdout`.

INCLUDE FILES `stdio.h`

putenv()

RETURNS The character written, or EOF if a write error occurs, with the error indicator set for the standard output stream.

SEE ALSO *ansiStdio*, *putc()*, *fputc()*

putenv()

NAME *putenv()* – set an environment variable

SYNOPSIS

```
STATUS putenv
(
    char * pEnvString /* string to add to env */
)
```

DESCRIPTION This routine sets an environment variable to a value by altering an existing variable or creating a new one. The parameter points to a string of the form "variableName=value". Unlike the UNIX implementation, the string is copied to a private buffer.

RETURNS OK, or ERROR if space cannot be malloc'd.

SEE ALSO *envLibInit()*, *getenv()*

puts()

NAME *puts()* – write a string to the standard output stream (ANSI)

SYNOPSIS

```
int puts
(
    char const * s /* string to write */
)
```

DESCRIPTION This routine writes to the standard output stream a specified string *s*, minus the terminating null character, and appends a new-line character to the output.

INCLUDE FILES *stdio.h*

RETURNS A non-negative value, or EOF if a write error occurs.

SEE ALSO *ansiStdio*, *fputs()*

putw()

NAME *putw()* – write a word (32-bit integer) to a stream

SYNOPSIS

```
int putw
(
    int    w, /* word (32-bit integer) */
    FILE * fp /* output stream */
)
```

DESCRIPTION This routine appends the 32-bit quantity *w* to a specified stream.
This routine is provided for compatibility with earlier VxWorks releases.

INCLUDE FILES `stdio.h`

RETURNS The value written.

SEE ALSO `ansiStdio`

pwd()

NAME *pwd()* – print the current default directory

SYNOPSIS `void pwd (void)`

DESCRIPTION This command displays the current working device/directory.

RETURNS N/A

SEE ALSO `usrLib`, `cd()`, *VxWorks Programmer's Guide: Target Shell*, `windsh`, *Tornado User's Guide: Shell*

qsort()

qsort()**NAME** `qsort()` – sort an array of objects (ANSI)

SYNOPSIS

```
void qsort
(
    void *                bot, /* initial element in array */
    size_t                nmemb, /* no. of objects in array */
    size_t                size, /* size of array element */
    int (* compar) (const void * ,
    const void *          ) /* comparison function */
)
```

DESCRIPTION This routine sorts an array of *nmemb* objects, the initial element of which is pointed to by *bot*. The size of each object is specified by *size*.

The contents of the array are sorted into ascending order according to a comparison function pointed to by *compar*, which is called with two arguments that point to the objects being compared. The function shall return an integer less than, equal to, or greater than zero if the first argument is considered to be respectively less than, equal to, or greater than the second.

If two elements compare as equal, their order in the sorted array is unspecified.

INCLUDE FILES `stdlib.h`**RETURNS** N/A**SEE ALSO** `ansiStdlib`

r0()**NAME** `r0()` – return the contents of register **r0** (also **r1** – **r14**) (ARM)

SYNOPSIS

```
int r0
(
    int taskId /* task ID, 0 means default task */
)
```

DESCRIPTION This command extracts the contents of register **r0** from the TCB of a specified task. If *taskId* is omitted or zero, the last task referenced is assumed.

Similar routines are provided for registers (**r1** – **r14**): *r1()* – *r14()*.

RETURNS The contents of register **r0** (or the requested register).

SEE ALSO **dbgArchLib**, *VxWorks Programmer's Guide: Debugging*

r3()

NAME *r3()* – return the contents of register **r3** (also **r4** – **r15**) (i960)

SYNOPSIS

```
int r3
(
    int taskId /* task ID, 0 means default task */
)
```

DESCRIPTION This command extracts the contents of register **r3** from the TCB of a specified task. If *taskId* is omitted or 0, the current default task is assumed.

Routines are provided for all local registers (**r3** – **r15**): *r3()* – *r15()*.

RETURNS The contents of the **r3** register (or the requested register).

SEE ALSO **dbgArchLib**, *VxWorks Programmer's Guide: Target Shell*

raise()

NAME *raise()* – send a signal to the caller's task

SYNOPSIS

```
int raise
(
    int signo /* signal to send to caller's task */
)
```

DESCRIPTION This routine sends the signal *signo* to the task invoking the call.

RETURNS OK (0), or ERROR (-1) if the signal number or task ID is invalid.

ERRNO EINVAL

SEE ALSO **sigLib**

ramDevCreate()

NAME *ramDevCreate()* – create a RAM disk device

SYNOPSIS

```
BLK_DEV *ramDevCreate
(
    char * ramAddr,      /* where it is in memory (0 = malloc) */
    int   bytesPerBlk,  /* number of bytes per block */
    int   blksPerTrack, /* number of blocks per track */
    int   nBlocks,      /* number of blocks on this device */
    int   blkOffset     /* no. of blks to skip at start of device */
)
```

DESCRIPTION This routine creates a RAM disk device.

Memory for the RAM disk can be pre-allocated separately; if so, the *ramAddr* parameter should be the address of the pre-allocated device memory. Or, memory can be automatically allocated with *malloc()* by setting *ramAddr* to zero.

The *bytesPerBlk* parameter specifies the size of each logical block on the RAM disk. If *bytesPerBlk* is zero, 512 is used.

The *blksPerTrack* parameter specifies the number of blocks on each logical track of the RAM disk. If *blksPerTrack* is zero, the count of blocks per track is set to *nBlocks* (i.e., the disk is defined as having only one track).

The *nBlocks* parameter specifies the size of the disk, in blocks. If *nBlocks* is zero, a default size is used. The default is calculated using a total disk size of either 51,200 bytes or one-half of the size of the largest memory area available, whichever is less. This default disk size is then divided by *bytesPerBlk* to determine the number of blocks.

The *blkOffset* parameter specifies an offset, in blocks, from the start of the device to be used when writing or reading the RAM disk. This offset is added to the block numbers passed by the file system during disk accesses. (VxWorks file systems always use block numbers beginning at zero for the start of a device.) This offset value is typically useful only if a specific address is given for *ramAddr*. Normally, *blkOffset* is 0.

FILE SYSTEMS Once the device has been created, it must be associated with a name and a file system (dosFs, rt11Fs, or rawFs). This is accomplished using the file system's device initialization routine or make-file-system routine, e.g., *dosFsDevInit()* or *dosFsMkfs()*. The *ramDevCreate()* call returns a pointer to a block device structure (BLK_DEV). This structure contains fields that describe the physical properties of a disk device and specify the addresses of routines within the **ramDrv** driver. The BLK_DEV structure address must be passed to the desired file system (dosFs, rt11Fs or rawFs) via the file system's device initialization or make-file-system routine. Only then is a name and file system associated with the device, making it available for use.

EXAMPLE

In the following example, a 200-Kbyte RAM disk is created with automatically allocated memory, 512-byte blocks, a single track, and no block offset. The device is then initialized for use with dosFs and assigned the name "DEV1:":

```
BLK_DEV *pBlkDev;
DOS_VOL_DESC *pVolDesc;
pBlkDev = ramDevCreate (0, 512, 400, 400, 0);
pVolDesc = dosFsMkfs ("DEV1:", pBlkDev);
```

The *dosFsMkfs()* routine calls *dosFsDevInit()* with default parameters and initializes the file system on the disk by calling *ioctl()* with the **FIODISKINIT** function.

If the RAM disk memory already contains a disk image created elsewhere, the first argument to *ramDevCreate()* should be the address in memory, and the formatting parameters -- *bytesPerBlk*, *blksPerTrack*, *nBlocks*, and *blkOffset* -- must be identical to those used when the image was created. For example:

```
pBlkDev = ramDevCreate (0xc0000, 512, 400, 400, 0);
pVolDesc = dosFsDevInit ("DEV1:", pBlkDev, NULL);
```

In this case, *dosFsDevInit()* must be used instead of *dosFsMkfs()*, because the file system already exists on the disk and should not be re-initialized. This procedure is useful if a RAM disk is to be created at the same address used in a previous boot of VxWorks. The contents of the RAM disk will then be preserved.

These same procedures apply when creating a RAM disk with *rt11Fs* using *rt11FsDevInit()* and *rt11FsMkfs()*, or creating a RAM disk with *rawFs* using *rawFsDevInit()*.

RETURNS

A pointer to a block device structure (**BLK_DEV**) or **NULL** if memory cannot be allocated for the device structure or for the RAM disk.

SEE ALSO

ramDrv, *dosFsMkfs()*, *dosFsDevInit()*, *rt11FsDevInit()*, *rt11FsMkfs()*, *rawFsDevInit()*

ramDrv()

NAME

ramDrv() – prepare a RAM disk driver for use (optional)

SYNOPSIS

STATUS *ramDrv* (void)

DESCRIPTION

This routine performs no real function, except to provide compatibility with earlier versions of **ramDrv** and to parallel the initialization function found in true disk device drivers. It also is used in **usrConfig.c** to link in the RAM disk driver when building VxWorks. Otherwise, there is no need to call this routine before using the RAM disk driver.

rand()

RETURNS OK, always.

SEE ALSO **ramDrv**

rand()

NAME *rand()* – generate a pseudo-random integer between 0 and **RAND_MAX** (ANSI)

SYNOPSIS `int rand (void)`

DESCRIPTION This routine generates a pseudo-random integer between 0 and **RAND_MAX**. The seed value for *rand()* can be reset with *srand()*.

INCLUDE FILES **stdlib.h**

RETURNS A pseudo-random integer.

SEE ALSO **ansiStdlib**, *srand()*

rawFsDevInit()

NAME *rawFsDevInit()* – associate a block device with raw volume functions

SYNOPSIS `RAW_VOL_DESC *rawFsDevInit`
`(`
`char * volName, /* volume name */`
`BLK_DEV * pBlkDev /* pointer to block device info */`
`)`

DESCRIPTION This routine takes a block device created by a device driver and defines it as a raw file system volume. As a result, when high-level I/O operations, such as *open()* and *write()*, are performed on the device, the calls will be routed through **rawFsLib**.

This routine associates *volName* with a device and installs it in the VxWorks I/O System's device table. The driver number used when the device is added to the table is that which was assigned to the raw library during *rawFsInit()*. (The driver number is kept in the global variable **rawFsDrvNum**.)

The **BLK_DEV** structure specified by *pBlkDev* contains configuration data describing the device and the addresses of five routines which will be called to read blocks, write blocks,

reset the device, check device status, and perform other control functions (*ioctl()*). These routines will not be called until they are required by subsequent I/O operations.

RETURNS A pointer to the volume descriptor (**RAW_VOL_DESC**), or NULL if there is an error.

SEE ALSO **rawFsLib**

rawFsInit()

NAME *rawFsInit()* – prepare to use the raw volume library

SYNOPSIS

```
STATUS rawFsInit
(
    int maxFiles /* max no. of simultaneously open files */
)
```

DESCRIPTION This routine initializes the raw volume library. It must be called exactly once, before any other routine in the library. The argument specifies the number of file descriptors that may be open at once. This routine allocates and sets up the necessary memory structures and initializes semaphores.

This routine also installs raw volume library routines in the VxWorks I/O system driver table. The driver number assigned to **rawFsLib** is placed in the global variable **rawFsDrvNum**. This number will later be associated with system file descriptors opened to rawFs devices.

This initialization is enabled when the configuration macro **INCLUDE_RAWFS** is defined; *rawFsInit()* is then called from the root task, *usrRoot()*, in *usrConfig.c*.

RETURNS OK or ERROR.

SEE ALSO **rawFsLib**

rawFsModeChange()

NAME *rawFsModeChange()* – modify the mode of a raw device volume

SYNOPSIS

```
void rawFsModeChange
(
    RAW_VOL_DESC * vdptr, /* pointer to volume descriptor */
)
```

```
int          newMode /* O_RDONLY/O_WRONLY/O_RDWR (both) */  
)
```

DESCRIPTION This routine sets the device's mode to *newMode* by setting the mode field in the `BLK_DEV` structure. This routine should be called whenever the read and write capabilities are determined, usually after a ready change.

The driver's device initialization routine should initially set the mode to `O_RDWR` (i.e., both `O_RDONLY` and `O_WRONLY`).

RETURNS N/A

SEE ALSO `rawFsLib`, `rawFsReadyChange()`

rawFsReadyChange()

NAME `rawFsReadyChange()` – notify `rawFsLib` of a change in ready status

SYNOPSIS

```
void rawFsReadyChange  
(  
    RAW_VOL_DESC * vdptr /* pointer to volume descriptor */  
)
```

DESCRIPTION This routine sets the volume descriptor state to `RAW_VD_READY_CHANGED`. It should be called whenever a driver senses that a device has come on-line or gone off-line, (e.g., a disk has been inserted or removed).

After this routine has been called, the next attempt to use the volume will result in an attempted remount.

RETURNS N/A

SEE ALSO `rawFsLib`

rawFsVolUnmount()

NAME *rawFsVolUnmount()* – disable a raw device volume

SYNOPSIS

```
STATUS rawFsVolUnmount
(
    RAW_VOL_DESC * vdptr /* pointer to volume descriptor */
)
```

DESCRIPTION This routine is called when I/O operations on a volume are to be discontinued. This is commonly done before changing removable disks. All buffered data for the volume is written to the device (if possible), any open file descriptors are marked as obsolete, and the volume is marked as not mounted.

Because this routine will flush data from memory to the physical device, it should not be used in situations where the disk-change is not recognized until after a new disk has been inserted. In these circumstances, use the ready-change mechanism. (See the manual entry for *rawFsReadyChange()*.)

This routine may also be called by issuing an *ioctl()* call using the **FIOUNMOUNT** function code.

RETURNS OK, or ERROR if the routine cannot access the volume.

SEE ALSO *rawFsLib*, *rawFsReadyChange()*

rcmd()

NAME *rcmd()* – execute a shell command on a remote machine

SYNOPSIS

```
int rcmd
(
    char * host,          /* host name or inet address */
    int  remotePort,    /* remote port to connect to (rshd) */
    char * localUser,   /* local user name */
    char * remoteUser,  /* remote user name */
    char * cmd,         /* command */
    int * fd2p          /* if this pointer is non-zero, stderr socket is */
                      /* and socket descriptor is filled in */
)
```

read()

- DESCRIPTION** This routine executes a command on a remote machine, using the remote shell daemon, *rshd*, on the remote system. It is analogous to the UNIX routine *rcmd()*.
- RETURNS** A socket descriptor if the remote shell daemon accepts, or ERROR if the remote command fails.
- SEE ALSO** *remLib*, UNIX BSD 4.3 manual entry for *rcmd()*

read()

NAME *read()* – read bytes from a file or device

SYNOPSIS

```
int read
(
    int fd,          /* file descriptor from which to read */
    char * buffer,  /* pointer to buffer to receive bytes */
    size_t maxbytes /* max no. of bytes to read into buffer */
)
```

DESCRIPTION This routine reads a number of bytes (less than or equal to *maxbytes*) from a specified file descriptor and places them in *buffer*. It calls the device driver to do the work.

RETURNS The number of bytes read (between 1 and *maxbytes*, 0 if end of file), or ERROR if the file descriptor does not exist, the driver does not have a read routines, or the driver returns ERROR. If the driver does not have a read routine, *errno* is set to ENOTSUP.

SEE ALSO *ioLib*

readdir()

NAME *readdir()* – read one entry from a directory (POSIX)

SYNOPSIS

```
struct dirent *readdir
(
    DIR * pDir /* pointer to directory descriptor */
)
```

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | <p>This routine obtains directory entry data for the next file from an open directory. The <i>pDir</i> parameter is the pointer to a directory descriptor (DIR) which was returned by a previous <i>opendir()</i>.</p> <p>This routine returns a pointer to a dirent structure which contains the name of the next file. Empty directory entries and MS-DOS volume label entries are not reported. The name of the file (or subdirectory) described by the directory entry is returned in the d_name field of the dirent structure. The name is a single null-terminated string.</p> <p>The returned dirent pointer will be NULL, if it is at the end of the directory or if an error occurred. Because there are two conditions which might cause NULL to be returned, the task's error number (errno) must be used to determine if there was an actual error. Before calling <i>readdir()</i>, set errno to OK. If a NULL pointer is returned, check the new value of errno. If errno is still OK, the end of the directory was reached; if not, errno contains the error code for an actual error which occurred.</p> |
| RETURNS | A pointer to a dirent structure, or NULL if there is an end-of-directory marker or error. |
| SEE ALSO | <i>dirLib</i> , <i>opendir()</i> , <i>closedir()</i> , <i>rewinddir()</i> , <i>ls()</i> |

realloc()

| | |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>realloc()</i> – reallocate a block of memory (ANSI) |
| SYNOPSIS | <pre>void *realloc (void * pBlock, /* block to reallocate */ size_t newSize /* new block size */)</pre> |
| DESCRIPTION | <p>This routine changes the size of a specified block of memory and returns a pointer to the new block of memory. The contents that fit inside the new size (or old size if smaller) remain unchanged. The memory alignment of the new block is not guaranteed to be the same as the original block.</p> |
| RETURNS | A pointer to the new block of memory, or NULL if the call fails. |
| SEE ALSO | memLib , <i>American National Standard for Information Systems – Programming Language – C, ANSI X3.159-1989: General Utilities (stdlib.h)</i> |

reboot()

NAME *reboot()* – reset network devices and transfer control to boot ROMs

SYNOPSIS

```
void reboot
(
    int startType /* how the boot ROMS will reboot */
)
```

DESCRIPTION This routine returns control to the boot ROMs after calling a series of preliminary shutdown routines that have been added via *rebootHookAdd()*, including routines to reset all network devices. After calling the shutdown routines, interrupts are locked, all caches are cleared, and control is transferred to the boot ROMs.

The bit values for *startType* are defined in **sysLib.h**:

BOOT_NORMAL (0x00)

causes the system to go through the countdown sequence and try to reboot VxWorks automatically. Memory is not cleared.

BOOT_NO_AUTOBOOT (0x01)

causes the system to display the VxWorks boot prompt and wait for user input to the boot ROM monitor. Memory is not cleared.

BOOT_CLEAR (0x02)

the same as **BOOT_NORMAL**, except that memory is cleared.

BOOT_QUICK_AUTOBOOT (0x04)

the same as **BOOT_NORMAL**, except the countdown is shorter.

RETURNS N/A

SEE ALSO *rebootLib*, *sysToMonitor()*, *rebootHookAdd()*, *VxWorks Programmer's Guide: Target Shell*, *windsh*, *Tornado User's Guide: Shell*

rebootHookAdd()

NAME *rebootHookAdd()* – add a routine to be called at reboot

SYNOPSIS

```
STATUS rebootHookAdd
(
    FUNCPTR rebootHook /* routine to be called at reboot */
)
```

DESCRIPTION This routine adds the specified routine to a list of routines to be called when VxWorks is rebooted. The specified routine should be declared as follows:

```
void rebootHook
(
    int startType /* startType is passed to all hooks */
)
```

RETURNS OK, or ERROR if memory is insufficient.

SEE ALSO *rebootLib, reboot()*

recv()

NAME *recv()* – receive data from a socket

SYNOPSIS

```
int recv
(
    int s, /* socket to receive data from */
    char * buf, /* buffer to write data to */
    int bufLen, /* length of buffer */
    int flags /* flags to underlying protocols */
)
```

DESCRIPTION This routine receives data from a connection-based (stream) socket.

The maximum length of *buf* is subject to the limits on TCP buffer size; see the discussion of `SO_RCVBUF` in the *setsockopt()* manual entry.

You may OR the following values into the *flags* parameter with this operation:

MSG_OOB (0x1)
Out-of-band data.

MSG_PEEK (0x2)
Return data without removing it from socket.

RETURNS The number of bytes received, or ERROR if the call fails.

SEE ALSO *sockLib, setsockopt()*

recvfrom()

NAME *recvfrom()* – receive a message from a socket

SYNOPSIS

```
int recvfrom
(
    int          s,          /* socket to receive from */
    char *       buf,       /* pointer to data buffer */
    int          bufLen,    /* length of buffer */
    int          flags,     /* flags to underlying protocols */
    struct sockaddr * from, /* where to copy sender's addr */
    int *        pFromLen /* value/result length of from */
)
```

DESCRIPTION This routine receives a message from a datagram socket regardless of whether it is connected. If *from* is non-zero, the address of the sender's socket is copied to it. The value-result parameter *pFromLen* should be initialized to the size of the *from* buffer. On return, *pFromLen* contains the actual size of the address stored in *from*.

The maximum length of *buf* is subject to the limits on UDP buffer size; see the discussion of `SO_RCVBUF` in the *setsockopt()* manual entry.

You may OR the following values into the *flags* parameter with this operation:

`MSG_OOB` (0x1) Out-of-band data.

`MSG_PEEK` (0x2) Return data without removing it from socket.

RETURNS The number of number of bytes received, or `ERROR` if the call fails.

SEE ALSO *sockLib*, *setsockopt()*

recvmsg()

NAME *recvmsg()* – receive a message from a socket

SYNOPSIS

```
int recvmsg
(
    int          sd, /* socket to receive from */
    struct msghdr * mp, /* scatter-gather message header */
    int          flags /* flags to underlying protocols */
)
```

- DESCRIPTION** This routine receives a message from a datagram socket. It may be used in place of *recvfrom()* to decrease the overhead of breaking down the message-header structure *msg_hdr* for each message.
- For BSD 4.4 sockets a copy of the *mp>msg_iov* array will be made. This requires a cluster from the network stack system pool of *size mp>msg_iovlen * sizeof (struct iovec)* or 8 bytes.
- RETURNS** The number of bytes received, or ERROR if the call fails.
- SEE ALSO** *sockLib*

reld()

- NAME** *reld()* – reload an object module
- SYNOPSIS**
- ```
MODULE_ID reld
(
 void * nameOrId, /* name or ID of the object module file */
 int options /* options, currently unused */
)
```
- DESCRIPTION** This routine unloads a specified object module from the system, and then calls *ld()* to load a new copy of the same name.
- If the file was originally loaded using a complete pathname, then *reld()* will use the complete name to locate the file. If the file was originally loaded using a partial pathname, then the current working directory must be changed to the working directory in use at the time of the original load.
- RETURNS** A module ID (type *MODULE\_ID*), or NULL.
- SEE ALSO** *unldLib*, *unld()*

## **remCurIdGet()**

**NAME** *remCurIdGet()* – get the current user name and password

**SYNOPSIS**

```
void remCurIdGet
(
 char * user, /* where to return current user name */
 char * passwd /* where to return current password */
)
```

**DESCRIPTION** This routine gets the user name and password currently used for remote host access privileges and copies them to *user* and *passwd*. Either parameter can be initialized to NULL, and the corresponding item will not be passed.

**RETURNS** N/A

**SEE ALSO** *remLib*, *iam()*, *whoami()*

---

## **remCurIdSet()**

**NAME** *remCurIdSet()* – set the remote user name and password

**SYNOPSIS**

```
STATUS remCurIdSet
(
 char * newUser, /* user name to use on remote */
 char * newPasswd /* password to use on remote (NULL = none) */
)
```

**DESCRIPTION** This routine specifies the user name that will have access privileges on the remote machine. The user name must exist in the remote machine's */etc/passwd*, and if it has been assigned a password, the password must be specified in *newPasswd*. Either parameter can be NULL, and the corresponding item will not be set.

The maximum length of the user name and the password is **MAX\_IDENTITY\_LEN**(defined in *remLib.h*).

**NOTE** A more convenient version of this routine is *iam()*, intended for use from the shell.

**RETURNS** OK, or ERROR if the name or password is too long.

**SEE ALSO** *remLib*, *iam()*, *whoami()*

---

## *remove()*

|                    |                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>remove()</i> – remove a file (ANSI)                                                                                                                  |
| <b>SYNOPSIS</b>    | <pre>STATUS remove (     const char * name /* name of the file to remove */ )</pre>                                                                     |
| <b>DESCRIPTION</b> | This routine deletes a specified file. It calls the driver for the particular device on which the file is located to do the work.                       |
| <b>RETURNS</b>     | OK if there is no delete routine for the device or the driver returns OK; ERROR if there is no such device or the driver returns ERROR.                 |
| <b>SEE ALSO</b>    | <i>ioLib</i> , <i>American National Standard for Information Systems – Programming Language – C</i> , <i>ANSI X3.159-1989: Input/Output (stdio.h)</i> , |

---

## *rename()*

|                    |                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>rename()</i> – change the name of a file                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <pre>int rename (     const char * oldname, /* name of file to rename */     const char * newname /* name with which to rename file */ )</pre>                                                                                                                                                                      |
| <b>DESCRIPTION</b> | This routine changes the name of a file from <i>oldfile</i> to <i>newfile</i> .                                                                                                                                                                                                                                     |
| <b>NOTE</b>        | Only certain devices support <i>rename()</i> . To confirm that your device supports it, consult the respective <i>xxDrv</i> or <i>xxFs</i> listings to verify that <i>ioctl FIORENAME</i> exists. For example, <i>dosFs</i> and <i>rt11Fs</i> support <i>rename()</i> , but <i>netDrv</i> and <i>nfsDrv</i> do not. |
| <b>RETURNS</b>     | OK, or ERROR if the file could not be opened or renamed.                                                                                                                                                                                                                                                            |
| <b>SEE ALSO</b>    | <i>ioLib</i>                                                                                                                                                                                                                                                                                                        |

## *repeat()*

**NAME** *repeat()* – spawn a task to call a function repeatedly

**SYNOPSIS**

```
int repeat
(
 int n, /* no. of times to call func (0=forever) */
 FUNCPTR func, /* function to call repeatedly */
 int arg1, /* first of eight args to pass to func */
 int arg2,
 int arg3,
 int arg4,
 int arg5,
 int arg6,
 int arg7,
 int arg8
)
```

**DESCRIPTION** This command spawns a task that calls a specified function *n* times, with up to eight of its arguments. If *n* is 0, the routine is called endlessly, or until the spawned task is deleted.

**NOTE** The task is spawned using *sp()*. See the description of *sp()* for details about priority, options, stack size, and task ID.

**RETURNS** A task ID, or ERROR if the task cannot be spawned.

**SEE ALSO** *usrLib*, *repeatRun()*, *sp()*, *VxWorks Programmer's Guide: Target Shell*, *windsh*, *Tornado User's Guide: Shell*

---

## *repeatRun()*

**NAME** *repeatRun()* – call a function repeatedly

**SYNOPSIS**

```
void repeatRun
(
 int n, /* no. of times to call func (0=forever) */
 FUNCPTR func, /* function to call repeatedly */
 int arg1, /* first of eight args to pass to func */
 int arg2,
 int arg3,
```

```

int arg4,
int arg5,
int arg6,
int arg7,
int arg8
)

```

- DESCRIPTION** This command calls a specified function *n* times, with up to eight of its arguments. If *n* is 0, the routine is called endlessly.
- Normally, this routine is called only by *repeat()*, which spawns it as a task.
- RETURNS** N/A
- SEE ALSO** *usrLib*, *repeat()*, *VxWorks Programmer's Guide: Target Shell*

---

## *resolvDNComp()*

- NAME** *resolvDNComp()* – compress a DNS name in a DNS packet
- SYNOPSIS**
- ```

int resolvDNComp
(
    const u_char * exp_dn, /* ptr to the expanded domain name */
    u_char *      comp_dn, /* ptr to where to output the compressed name */
    int          length,  /* length of the buffer pointed by comp_dn */
    u_char * *   dnptrs,  /* ptr to a ptr list of compressed names */
    u_char * *   lastdnptr /* ptr to the last entry pointed by dnptrs */
)

```
- DESCRIPTION** This routine takes the expanded domain name referenced in the *exp_dn* parameter, compresses it, and stores the compressed name in the location pointed to by the *comp_dn* parameter. The *length* parameter passes in the length of the buffer starting at *comp_dn*. The *dnptrs* parameter is a pointer to a list of pointers to previously compressed names. The *lastdnptr* parameter points to the last entry in the *dnptrs* array.
- RETURNS** The size of the compressed name, or ERROR.
- SEE ALSO** *resolvLib*, *resolvGetHostByName()*, *resolvGetHostByAddr()*, *resolvDNExpand()*, *resolvInit()*, *resolvSend()*, *resolvParamsSet()*, *resolvParamsGet()*, *resolvMkQuery()*, *resolvQuery()*

resolvDNExpand()

NAME *resolvDNExpand()* – expand a DNS compressed name from a DNS packet

SYNOPSIS

```
int resolvDNExpand
(
    const u_char * msg,      /* ptr to the start of the DNS packet */
    const u_char * eomorig, /* ptr to last location +1 of the DNS packet */
    const u_char * comp_dn, /* ptr to the compressed domain name */
    u_char *      exp_dn,   /* ptr to where the expanded DN is output */
    int           length    /* length of the buffer pointed by exp_dn */
)
```

DESCRIPTION This function expands a compressed DNS name from a DNS packet. The *msg* parameter points to that start of the DNS packet. The *eomorig* parameter points to the last location of the DNS packet plus 1. The *comp_dn* parameter points to the compressed domain name, and *exp_dn* parameter expects a pointer to a buffer. Upon function completion, this buffer contains the expanded domain name. Use the *length* parameter to pass in the size of the buffer referenced by the *exp_dn* parameter.

RETURNS The length of the expanded domain name, or ERROR on failure.

SEE ALSO *resolvLib*, *resolvGetHostByName()*, *resolvGetHostByAddr()*, *resolvInit()*, *resolvDNComp()*, *resolvSend()*, *resolvParamsSet()*, *resolvParamsGet()*, *resolvMkQuery()*, *resolvQuery()*

resolvGetHostByAddr()

NAME *resolvGetHostByAddr()* – query the DNS server for the host name of an IP address

SYNOPSIS

```
struct hostent * resolvGetHostByAddr
(
    const char * pInetAddr,
    char *      pHostBuf,
    int         bufLen
)
```

DESCRIPTION This function returns a **hostent** structure, which is defined as follows:

```
struct hostent
{
```

```

char *   h_name;           /* official name of host */
char **  h_aliases;       /* alias list */
int      h_addrtype;      /* address type */
int      h_length;        /* length of address */
char **  h_addr_list;     /* list of addresses from name server */
unsigned int h_ttl;       /* Time to Live in Seconds for this entry */
}

```

The `h_aliases` and `h_addr_type` vectors are NULL-terminated.

The `pinetAddr` parameter passes in the IP address (in network byte order) for the host whose name you want to discover. The `pBuf` and `bufLen` parameters specify the location and size (512 bytes or more) of the buffer that is to receive the `hostent` structure. `resolvGetHostByAddr()` returns host addresses are returned in network byte order.

| | |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RETURNS | A pointer to a <code>hostent</code> structure if the host is found, or NULL if the parameters are invalid, host is not found, or the buffer is too small. |
| ERRNO | <p> <code>S_resolvLib_INVALID_PARAMETER</code> <code>S_resolvLib_BUFFER_2_SMALL</code> <code>S_resolvLib_TRY_AGAIN</code> <code>S_resolvLib_HOST_NOT_FOUND</code> <code>S_resolvLib_NO_DATA</code> <code>S_resolvLib_NO_RECOVERY</code> </p> |
| SEE ALSO | <code>resolvLib</code> , <code>resolvGetHostByName()</code> , <code>resolvInit()</code> , <code>resolvDNExpand()</code> , <code>resolvDNComp()</code> , <code>resolvSend()</code> , <code>resolvParamsSet()</code> , <code>resolvParamsGet()</code> , <code>resolvMkQuery()</code> , <code>resolvQuery()</code> |

resolvGetHostByName()

NAME `resolvGetHostByName()` – query the DNS server for the IP address of a host

SYNOPSIS

```

struct hostent * resolvGetHostByName
(
    char * pHostName, /* ptr to the name of the host */
    char * pHostBuf,  /* ptr to the buffer used by hostent structure */
    int   bufLen      /* length of the buffer */
)

```

DESCRIPTION This function returns a `hostent` structure. This structure is defined as follows:

```

struct hostent
{
    char *   h_name;           /* official name of host */

```

resolvInit()

```

char ** h_aliases;      /* alias list */
int     h_addrtype;    /* address type */
int     h_length;      /* length of address */
char ** h_addr_list;   /* list of addresses from name server */
unsigned int h_ttl;    /* Time to Live in Seconds for this entry */
}

```

The **h_aliases** and **h_addr_type** vectors are NULL-terminated.

Specify the host you want to query in *pHostname*. Use *pBuf* and *bufLen* to specify the location and size of a buffer to receive the **hostent** structure and its associated contents. Host addresses are returned in network byte order. Given the information this routine retrieves, the *pBuf* buffer should be 512 bytes or larger.

- RETURNS** A pointer to a **hostent** structure if the host is found, or NULL if the parameters are invalid, the host is not found, or the buffer is too small.
- ERRNO** S_resolvLib_INVALID_PARAMETER
S_resolvLib_BUFFER_2_SMALL
S_resolvLib_TRY_AGAIN
S_resolvLib_HOST_NOT_FOUND
S_resolvLib_NO_DATA
S_resolvLib_NO_RECOVERY
- SEE ALSO** resolvLib, resolvInit(), resolvGetHostByAddr(), resolvDNExpand(), resolvDNComp(), resolvSend(), resolvParamsSet(), resolvParamsGet(), resolvMkQuery(), resolvQuery()

resolvInit()

- NAME** *resolvInit()* – initialize the resolver library
- SYNOPSIS**
- ```

STATUS resolvInit
(
 char * pNameServer, /* pointer to Name server IP address */
 char * pDefaultDomainName, /* default domain name */
 FUNCPTR pdnsDebugRtn /* function ptr to debug routine */
)

```
- DESCRIPTION** This function initializes the resolver. *pNameServer* is a single IP address for a name server in dotted decimal notation. *pDefaultDomainName* is the default domain name to be appended to names without a dot. The function pointer *pdnsDebugRtn* is set to the resolver debug function. Additional name servers can be configured using the function *resolvParamsSet()*.

**RETURNS** OK or ERROR.

**SEE ALSO** *resolvLib*, *resolvGetHostByName()*, *resolvGetHostByAddr()*, *resolvDNExpand()*, *resolvDNComp()*, *resolvSend()*, *resolvParamsSet()*, *resolvParamsGet()*, *resolvQuery()*

---

## *resolvMkQuery()*

**NAME** *resolvMkQuery()* – create all types of DNS queries

**SYNOPSIS**

```
int resolvMkQuery
(
 int op, /* set to desire query QUERY or IQUERY */
 const char * dname, /* domain name to be use in the query */
 int class, /* query class for IP is C_IN */
 int type, /* type is T_A, T_PTR, ... */
 const char * data, /* resource Record (RR) data */
 int datalen, /* length of the RR */
 const char * newrr_in, /* not used always set to NULL */
 char * buf, /* out of the constructed query */
 int buflen /* length of the buffer for the query */
)
```

**DESCRIPTION** This routine uses the input parameters to create a domain name query. You can set the *op* parameter to QUERY or IQUERY. Specify the domain name in *dname*, the class in *class*, the query type in *type*. Valid values for type include T\_A, T\_PTR, and so on. Use *data* to add Resource Record data to the query. Use *datalen* to pass in the length of the data buffer. Set *newrr\_in* to NULL. This parameter is reserved for future use. The *buf* parameter expects a pointer to the output buffer for the constructed query. Use *buflen* to pass in the length of the buffer referenced in *buf*.

**RETURNS** The length of the constructed query or ERROR.

**SEE ALSO** *resolvLib*, *resolvGetHostByName()*, *resolvGetHostByAddr()*, *resolvDNExpand()*, *resolvDNComp()*, *resolvSend()*, *resolvParamsSet()*, *resolvParamsGet()*, *resolvInit()*, *resolvQuery()*

---

## *resolvParamsGet()*

**NAME** *resolvParamsGet()* – get the parameters which control the resolver library

**SYNOPSIS**

```
void resolvParamsGet
(
 RESOLV_PARAMS_S * pResolvParams /* ptr to resolver parameter struct */
)
```

**DESCRIPTION** This routine copies the resolver parameters to the **RESOLV\_PARAMS\_S** structure referenced in the *pResolvParams* parameter. The **RESOLV\_PARAMS\_S** structure is defined in **resolvLib.h** as follows:

```
typedef struct
{
 char queryOrder;
 char domainName [MAXDNAME];
 char nameServersAddr [MAXNS][MAXIPADDRLLEN];
} RESOLV_PARAMS_S;
```

Typically, you call this function just before calling *resolvParamsSet()*. The *resolvParamsGet()* call populates the **RESOLV\_PARAMS\_S** structure. You can then modify the default values just before calling *resolvParamsSet()*.

**RETURNS** N/A

**SEE ALSO** *resolvLib*, *resolvGetHostByName()*, *resolvGetHostByAddr()*, *resolvDNExpand()*, *resolvDNComp()*, *resolvSend()*, *resolvParamsSet()*, *resolvInit()*, *resolvMkQuery()*, *resolvQuery()*

---

## *resolvParamsSet()*

**NAME** *resolvParamsSet()* – set the parameters which control the resolver library

**SYNOPSIS**

```
STATUS resolvParamsSet
(
 RESOLV_PARAMS_S * pResolvParams /* ptr to resolver parameter struct */
)
```

**DESCRIPTION** This routine sets the resolver parameters. *pResolvParams* passes in a pointer to a **RESOLV\_PARAMS\_S** structure, which is defined as follows:

```
typedef struct
{
 char queryOrder;
 char domainName [MAXDNAME];
 char nameServersAddr [MAXNS][MAXIPADDRLLEN];
} RESOLV_PARAMS_S;
```

Use the members of this structure to specify the settings you want to apply to the resolver. It is important to remember that multiple tasks can use the resolver library and that the settings specified in this `RESOLV_PARAMS_S` structure affect all queries from all tasks. In addition, you should set resolver parameters at initialization and not while queries could be in progress. Otherwise, the results of the query are unpredictable.

Before calling *resolvParamsSet()*, you should first call *resolvParamsGet()* to populate a `RESOLV_PARAMS_S` structure with the current settings. Then you change the values of the members that interest you.

Valid values for the `queryOrder` member of `RESOLV_PARAMS_S` structure are defined in `resolvLib.h`. Set the `domainName` member to the domain to which this resolver belongs. Set the `nameServersAddr` member to the IP addresses of the DNS server that the resolver can query. You must specify the IP addresses in standard dotted decimal notation. This function tries to validate the values in the `queryOrder` and `nameServerAddr` members. This function does not try to validate the domain name.

**RETURNS** OK if the parameters are valid, ERROR otherwise.

**SEE ALSO** *resolvLib*, *resolvGetHostByName()*, *resolvGetHostByAddr()*, *resolvDNExpand()*, *resolvDNComp()*, *resolvSend()*, *resolvInit()*, *resolvParamsGet()*, *resolvMkQuery()*, *resolvQuery()*

---

## *resolvQuery()*

**NAME** *resolvQuery()* – construct a query, send it, wait for a response

**SYNOPSIS**

```
int resolvQuery
(
 char * name, /* domain name */
 int class, /* query class for IP is C_IN */
 int type, /* type is T_A, T_PTR, ... */
 u_char * answer, /* buffer to put answer */
 int anslen /* length of answer buffer */
)
```

**resolvSend()**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | This routine constructs a query for the domain specified in the <i>name</i> parameter. The <i>class</i> parameter specifies the class of the query. The <i>type</i> parameter specifies the type of query. The routine then sends the query to the DNS server. When the server responds, the response is validated and copied to the buffer you supplied in the <i>answer</i> parameter. Use the <i>anslen</i> parameter to pass in the size of the buffer referenced in <i>answer</i> . |
| <b>RETURNS</b>     | The length of the response or ERROR.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>ERRNO</b>       | S_resolvLib_TRY_AGAIN<br>S_resolvLib_HOST_NOT_FOUND<br>S_resolvLib_NO_DATA<br>S_resolvLib_NO_RECOVERY                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SEE ALSO</b>    | resolvLib, resolvGetHostByName(), resolvGetHostByAddr(), resolvDNExpand(), resolvDNComp(), resolvInit(), resolvParamsSet(), resolvParamsGet(), resolvMkQuery()                                                                                                                                                                                                                                                                                                                           |

---

**resolvSend()**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>resolvSend()</i> – send a pre-formatted query and return the answer                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <pre>int resolvSend (     const char * buf,    /* pre-formatted query */     int        buflen, /* length of query */     char *     answer, /* buffer for answer */     int        anslen  /* length of answer */ )</pre>                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | This routine takes a pre-formatted DNS query and sends it to the domain server. Use <i>buf</i> to pass in a pointer to the query. Use <i>buflen</i> to pass in the size of the buffer referenced in <i>buf</i> . The <i>answer</i> parameter expects a pointer to a buffer into which this routine can write the answer retrieved from the server. Use <i>anslen</i> to pass in the size of the buffer you have provided in <i>anslen</i> . |
| <b>RETURNS</b>     | The length of the response or ERROR.                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>ERRNO</b>       | S_resolvLib_TRY_AGAIN<br>ECONNREFUSE<br>ETIMEDOU                                                                                                                                                                                                                                                                                                                                                                                            |

**SEE ALSO** *resolvLib*, *resolvGetHostByName()*, *resolvGetHostByAddr()*, *resolvDNExpand()*, *resolvDNComp()*, *resolvInit()*, *resolvParamsSet()*, *resolvParamsGet()*, *resolvMkQuery()*, *resolvQuery()*

---

## *rewind()*

**NAME** *rewind()* – set the file position indicator to the beginning of a file (ANSI)

**SYNOPSIS**

```
void rewind
(
 FILE * fp /* stream */
)
```

**DESCRIPTION** This routine sets the file position indicator for a specified stream to the beginning of the file.

It is equivalent to:

```
(void) fseek (fp, 0L, SEEK_SET);
```

except that the error indicator for the stream is cleared.

**INCLUDE FILES** *stdio.h*

**RETURNS** N/A

**SEE ALSO** *ansiStdio*, *fseek()*, *ftell()*

---

## *rewinddir()*

**NAME** *rewinddir()* – reset position to the start of a directory (POSIX)

**SYNOPSIS**

```
void rewinddir
(
 DIR * pDir /* pointer to directory descriptor */
)
```

**DESCRIPTION** This routine resets the position pointer in a directory descriptor (DIR). The *pDir* parameter is the directory descriptor pointer that was returned by *opendir()*.

As a result, the next *readdir()* will cause the current directory data to be read in again, as if an *opendir()* had just been performed. Any changes in the directory that have occurred since the initial *opendir()* will now be visible. The first entry in the directory will be returned by the next *readdir()*.

**RETURNS** N/A

**SEE ALSO** *dirLib*, *opendir()*, *readdir()*, *closedir()*

---

## ***rindex()***

**NAME** *rindex()* – find the last occurrence of a character in a string

**SYNOPSIS**

```
char *rindex
(
 const char * s, /* string in which to find character */
 int c /* character to find in string */
)
```

**DESCRIPTION** This routine finds the last occurrence of character *c* in string *s*.

**RETURNS** A pointer to *c*, or NULL if *c* is not found.

**SEE ALSO** *bLib*

---

## ***rip()***

**NAME** *rip()* – return the contents of register **rip** (i960)

**SYNOPSIS**

```
int rip
(
 int taskId /* task ID, 0 means default task */
)
```

**DESCRIPTION** This command extracts the contents of register **rip**, the return instruction pointer, from the TCB of a specified task. If *taskId* is omitted or 0, the current default task is assumed.

**RETURNS** The contents of the **rip** register.

SEE ALSO *dbgArchLib, VxWorks Programmer's Guide: Target Shell*

---

## *ripAuthHook()*

**NAME** *ripAuthHook()* – sample authentication hook

**SYNOPSIS**

```
STATUS ripAuthHook
(
 char * pKey, /* rip2IfConfAuthKey entry from MIB-II family */
 RIP_PKT * pRip /* received RIP message */
)
```

**DESCRIPTION** This hook demonstrates one possible authentication mechanism. It rejects all RIP-2 messages which used simple password authentication since they did not match the key contained in the MIB variable. All other RIP-2 messages are also rejected since no other authentication type is supported and all RIP-1 messages are also rejected, as recommended by the RFC specification. This behavior is the same as if no hook were installed.

**RETURNS** OK if message is acceptable, or ERROR otherwise.

**ERRNO** N/A

## *ripAuthHookAdd()*

**NAME** *ripAuthHookAdd()* – add an authentication hook to a RIP interface

**SYNOPSIS**

```
STATUS ripAuthHookAdd
(
 char* pIpAddr, /* IP address in dotted decimal notation */
 FUNCPTR pAuthHook /* routine to handle message authentication */
)
```

**DESCRIPTION** This routine installs a hook routine to validate incoming RIP messages for a registered interface given by *pIpAddr*. (Interfaces created or changed after a RIP session has started may be installed/updated with the *ripIfSearch()* and *ripIfReset()* routines). The hook is

only called if an SNMP agent enables authentication for the corresponding interface. It uses the following prototype:

```
STATUS ripAuthHookRtn (char *pKey, RIP_PKT *pRip);
```

The first argument contains the authentication key for the message stored in the rip2IfConfAuthKey MIB variable and the second argument uses the RIP\_PKT structure (defined in **rip/ripLib.h**) to access the message body. The routine must return OK if the message is acceptable, or ERROR otherwise. All RIP-2 messages sent to that routine already contain an authentication entry, but have not been verified. (Any unauthenticated RIP-2 messages have already been discarded as required by the RFC specification). RIP-1 messages may be accepted or rejected. RIP-2 messages requesting simple password authentication which match the key are accepted automatically before the hook is called. The remaining RIP-2 messages either did not match that key or are using an unknown authentication type. If any messages are rejected, the MIB-II counters are updated appropriately outside of the hook routine.

The current RIP implementation contains a sample authentication hook which may be added as follows:

```
if (ripAuthHookAdd ("90.0.0.1", ripAuthHook) == ERROR)
 logMsg ("Unable to add authorization hook.\n", 0, 0, 0, 0, 0, 0);
```

The sample routine only supports simple password authentication against the key included in the MIB variable. Since all such messages have already been accepted, all RIP-2 messages received by the routine are discarded. All RIP-1 messages are also discarded, so the hook actually has no effect. The body of that routine is:

```
STATUS ripAuthHook
(
 char * pKey, /* rip2IfConfAuthKey entry from MIB-II family */
 RIP_PKT * pRip /* received RIP message */
)
{
 if (pRip->rip_vers == 1)
 {
 /*
 * @ The RFC specification recommends, but does not require, rejecting
 * @ version 1 packets when authentication is enabled.
 */
 return (ERROR);
 }
 /*
 * @ The authentication type field in the RIP message corresponds to
 * @ the first two bytes of the sa_data field overlaid on that
 * @ message by the sockaddr structure contained within the RIP_PKT
 * @ structure (see rip/ripLib.h).
 */
 if ((pRip->rip_nets[0].rip_dst.sa_data[0] != 0) ||
```

```

 (pRip->rip_nets[0].rip_dst.sa_data[1] !=
M2_rip2IfConfAuthType_simplePassword)
 {
 /* Unrecognized authentication type. */
 return (ERROR);
 }
/*
 @ Discard version 2 packets requesting simple password authentication
 @ which did not match the MIB variable.
 */
return (ERROR);
}

```

A comparison against a different key could be performed as follows:

```

bzero ((char *)&key, AUTHKEYLEN); /* AUTHKEYLEN from rip/m2RipLib.h */
/*
 @ The start of the authorization key corresponds to the third byte
 @ of the sa_data field in the sockaddr structure overlayed on the
 @ body of the RIP message by the RIP_PKT structure. It continues
 @ for the final 14 bytes of that structure and the first two bytes
 @ of the following rip_metric field.
 */
bcopy ((char *)(pRip->rip_nets[0].rip_dst.sa_data + 2),
 (char *)&key, AUTHKEYLEN);
if (bcmp ((char *)key, privateKey, AUTHKEYLEN) != 0)
 {
 /* Key does not match: reject message. */
 return (ERROR);
 }
return (OK);

```

The *ripAuthHookDelete()* routine will remove the installed function. If authentication is still enabled for the interface, all incoming messages which do not use simple password authentication will be rejected until a routine is provided.

| <b>SYNOPSIS</b>    | <code>void ripFilterDisable (void)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>This routine configures an active RIP session to ignore the restrictions necessary for RIP-1 and RIP-2 routers to operate correctly in the same network. All border gateway filtering is ignored and all routes to subnets, supernets, and specific hosts will be sent over any available interface. This operation is only correct if no RIP-1 routers are present anywhere on the network. Results are unpredictable if that condition is not met, but high rates of packet loss and widespread routing failures are likely.</p> <p>The border gateway filtering rules are in force by default.</p> |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>DESCRIPTION</b> | <p>This routine configures an active RIP session to enforce the restrictions necessary for RIP-1 and RIP-2 routers to operate correctly in the same network as described in section 3.2 of RFC 1058 and section 3.3 of RFC 1723. When enabled, routes to portions of a logical network (including host routes) will be limited to routers within that network. Updates sent outside that network will only include a single entry representing the entire network. That entry will subsume all subnets and host-specific routes. If supernets are used, the entry will advertise the largest class-based portion of the supernet reachable through the connected interface.</p> |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>NAME</b>        | <i>ripIfReset()</i> – alter the RIP configuration after an interface changes                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <pre>STATUS ripIfReset (     char * pIfName /* name of changed interface */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | This routine updates the interface list and routing tables to reflect address and/or netmask changes for the device indicated by <i>pIfName</i> . To accommodate possible changes in the network number, all routes using the named interface are removed from the routing tables, but will be added in the next route update if appropriate. None of the removed routes are poisoned, so it may take some time for the routing tables of all the RIP participants to stabilize if the network number has changed. |
| <b>RETURNS</b>     | OK, or ERROR if named interface not found or not added to list.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>ERRNO</b>       | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SEE ALSO</b>    | <i>ripLib</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## *ripIfSearch()*

|                    |                                                                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>ripIfSearch()</i> – add new interfaces to the internal list                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <pre>void ripIfSearch (void)</pre>                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | By default, a RIP session will not recognize any interfaces initialized after it has started. This routine schedules a search for additional interfaces which will occur during the next update of the internal routing table. Once completed, the session will accept and send RIP messages over the new interfaces. |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                                                                   |
| <b>ERRNO</b>       | N/A                                                                                                                                                                                                                                                                                                                   |
| <b>SEE ALSO</b>    | <i>ripLib</i>                                                                                                                                                                                                                                                                                                         |

## *ripLeakHookAdd()*

**NAME** *ripLeakHookAdd()* – add a hook to bypass the RIP and kernel routing tables

**SYNOPSIS**

```
STATUS ripLeakHookAdd
(
 char * pIpAddr, /* IP address in dotted decimal notation */
 FUNCPTR pLeakHook /* function pointer to hook */
)
```

**DESCRIPTION** This routine installs a hook routine to support alternative routing protocols for the registered interface given by *pIpAddr*. (Interfaces created or changed after a RIP session has started may be installed/updated with the *ripIfSearch()* and *ripIfReset()* routines).

The hook uses the following interface:

```
STATUS ripLeakHookRtn (long dest, long gateway, long netmask)
```

The RIP session will not add the given route to any tables if the hook routine returns OK, but will create a route entry otherwise.

The *ripLeakHookDelete()* will allow the RIP session to add new routes unconditionally.

**RETURNS** OK, or ERROR if the interface could not be found.

**ERRNO** S\_m2Lib\_INVALID\_PARAMETER  
S\_m2Lib\_ENTRY\_NOT\_FOUND

**SEE ALSO** ripLib

---

## *ripLeakHookDelete()*

**NAME** *ripLeakHookDelete()* – remove a table bypass hook from a RIP interface

**SYNOPSIS**

```
STATUS ripLeakHookDelete
(
 char* pIpAddr /* IP address in dotted decimal notation */
)
```

**DESCRIPTION** This routine removes the assigned bypass hook from a registered interface indicated by *pIpAddr*. (Interfaces created or changed after a RIP session has started may be installed/updated with the *ripIfSearch()* and *ripIfReset()* routines). The RIP session will

return to the default behavior and add entries to the internal RIP table and kernel routing table unconditionally.

**RETURNS** OK, or ERROR if the interface could not be found.

**ERRNO** S\_m2Lib\_INVALID\_PARAMETER  
S\_m2Lib\_ENTRY\_NOT\_FOUND

**SEE ALSO** ripLib

---

## **ripLibInit()**

**NAME** *ripLibInit()* – initialize the RIP routing library

**SYNOPSIS**

```
STATUS ripLibInit
(
 BOOL supplier, /* operate in silent mode? */
 BOOL gateway, /* act as gateway to the Internet? */
 BOOL multicast, /* use multicast or broadcast addresses? */
 int version, /* 1 or 2: selects format of outgoing messages */
 int timerRate, /* update frequency for internal routing table */
 int supplyInterval, /* update frequency for neighboring routers */
 int expire, /* maximum interval for renewing learned routes */
 int garbage /* elapsed time before deleting stale route */
)
```

**DESCRIPTION** This routine creates and initializes the global data structures used by the RIP routing library and starts a RIP session to maintain routing tables for a host. It must be called before using any other library routines, and is invoked automatically if `INCLUDE_RIP` is defined at the time the system is built.

The resulting RIP session will monitor all network interfaces which are currently available for messages from other RIP routers. If the *supplier* parameter is true, it will also respond to specific requests from other routers and transmit route updates over every known interface at the interval specified by *supplyInterval*.

Specifying a *gateway* setting of true establishes this router as a gateway to the wider Internet, capable of routing packets anywhere within the local networks. The final *multicast* flag indicates whether the RIP messages are sent to the pre-defined multicast address of 224.0.0.9 (which requires a *version* setting of 2) or to the broadcast address of the interfaces.

The *version* parameter determines the format used for outgoing RIP messages, and also sets the initial settings of the MIB-II compatibility switches in combination with the

*multicast* flag. A *version* of 1 will restrict all incoming traffic to that older message type. A *version* of 2 will set the receive switch to accept either type unless *multicast* is true, which limits reception to version 2 messages only. SNMP agents may alter those settings on a per-interface basis once startup is complete.

The remaining parameters set various system timers used to maintain the routing table. All of the values are expressed in seconds, and must be greater than or equal to 1. The *timerRate* determines how often the routing table is examined for changes and expired routes. The *supplyInterval* must be an exact multiple of that value. The *expire* parameter specifies the maximum time between updates before a route is invalidated and removed from the kernel table. Expired routes are then deleted from the internal RIP routing table if no update has been received within the time set by the *garbage* parameter.

The defaults for all the parameter settings are given by the following constants. The default timer values match the settings indicated in the RFC specification.

| Parameter Name        | Default Value | Symbolic Constant   |
|-----------------------|---------------|---------------------|
| <i>supplier</i>       | 0 (FALSE)     | RIP_SUPPLIER        |
| <i>gateway</i>        | 0 (FALSE)     | RIP_GATEWAY         |
| <i>multicast</i>      | 0 (FALSE)     | RIP_EXPIRE_TIME     |
| <i>version</i>        | 1             | RIP_SUPPLY_INTERVAL |
| <i>timerRate</i>      | 1             | RIP_TIMER_RATE      |
| <i>supplyInterval</i> | 30            | RIP_SUPPLY_INTERVAL |
| <i>expire</i>         | 180           | RIP_EXPIRE_TIME     |
| <i>garbage</i>        | 300           | RIP_GARBAGE_TIME    |

**RETURNS** OK, or ERROR if configuration fails.

**ERRNO** N/A

## *ripRouteShow()*

**NAME** *ripRouteShow()* – display the internal routing table maintained by RIP

**SYNOPSIS** `void ripRouteShow()`

**DESCRIPTION** This routine prints every entry in the local RIP routing table. The flags displayed below the destination, gateway, and netmask addresses indicate the current route status. Entries with the `RTS_INTERFACE` flag indicate routes to directly connected networks which are

***ripSendHookAdd()***

generated locally. If `RTS_SUBNET` is set for an entry, it is subject to border gateway filtering (if enabled). When `RTS_INTERNAL` is also present, the corresponding entry is an "artificial" route created to supply distant networks with legitimate destinations if border filtering excludes the actual entry. Those entries are not copied to the kernel routing table. The `RTS_CHANGED` flag marks entries added or modified in the last timer interval which will be included in a triggered update.

|                 |               |
|-----------------|---------------|
| <b>RETURNS</b>  | N/A           |
| <b>ERRNO</b>    | N/A           |
| <b>SEE ALSO</b> | <b>ripLib</b> |

## ***ripSendHookAdd()***

**NAME** *ripSendHookAdd()* – add an update filter to a RIP interface

**SYNOPSIS**

```
STATUS ripSendHookAdd
(
 char* pIpAddr, /* IP address in dotted decimal notation */
 BOOL (*ripSendHook) (struct rt_entry* pRt) /* Routine to use. */
)
```

**DESCRIPTION** This routine installs a hook routine to screen individual route entries for inclusion in a periodic update. The routine is installed for the registered interface given by *pIpAddr*. (Interfaces created or changed after a RIP session has started may be installed/updated with the *ripIfSearch()* and *ripIfReset()* routines).

The hook uses the following prototype:

```
BOOL ripSendHookRtn (struct rt_entry* pRt);
```

If the hook returns `FALSE`, the route is not included in the update. Otherwise, it is included if it meets the other restrictions, such as simple split horizon and border gateway filtering. The *ripSendHookDelete()* routine removes this additional filter from the output processing.

|                 |                                                                                |
|-----------------|--------------------------------------------------------------------------------|
| <b>RETURNS</b>  | OK, or ERROR if the interface could not be found.                              |

| <b>NAME</b>        | <i>ripShutdown()</i> – terminate all RIP processing                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <pre>STATUS ripShutdown (void)</pre>                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | This routine "poisons" all routes in the current table by transmitting updates with an infinite metric for each entry over all available interfaces. It then halts all RIP processing and removes the associated tasks and data structures. When completed successfully, the RIP services are unavailable until restarted with the <i>ripLibInit()</i> routine. |
| <b>RETURNS</b>     | OK if shutdown completed, or ERROR otherwise.                                                                                                                                                                                                                                                                                                                   |
| <b>ERRNO</b>       | N/A                                                                                                                                                                                                                                                                                                                                                             |

| <b>SYNOPSIS</b>    | <pre>STATUS rlogin (     char * host /* name of host to connect to */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>This routine allows users to log in to a remote host. It may be called from the VxWorks shell as follows:</p> <pre>-&gt; rlogin "remoteSystem"</pre> <p>where <i>remoteSystem</i> is either a host name, which has been previously added to the remote host table by a call to <i>hostAdd()</i>, or an Internet address in dot notation (e.g., "90.0.0.2"). The remote system will be logged into with the current user name as set by a call to <i>iam()</i>. The user disconnects from the remote system by typing:</p> <pre>~.</pre> <p>as the only characters on the line, or by simply logging out from the remote system using <i>logout()</i>.</p> |
| <b>RETURNS</b>     | OK, or ERROR if the host is unknown, no privileged ports are available, the routine is unable to connect to the host, or the child process cannot be spawned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>NAME</b>        | <i>rlogind()</i> – the VxWorks remote login daemon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <pre>void rlogind (void)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p>This routine provides a facility for remote users to log in to VxWorks over the network. If the configuration macro <code>INCLUDE_RLOGIN</code> is defined, <i>rlogind()</i> is spawned by <i>rlogInit()</i> at boot time.</p> <p>Remote login requests will cause <b>stdin</b>, <b>stdout</b>, and <b>stderr</b> to be directed away from the console. When the remote user disconnects, <b>stdin</b>, <b>stdout</b>, and <b>stderr</b> are restored, and the shell is restarted. The <i>rlogind()</i> routine uses the remote user verification protocol specified by the UNIX remote shell daemon documentation, but ignores all the</p> |

information except the user name, which is used to set the VxWorks remote identity (see the manual entry for *iam()*).

The remote login daemon requires the existence of a pseudo-terminal device, which is created by *rlogInit()* before *rlogind()* is spawned. The *rlogind()* routine creates two child processes, *tRlogInTask* and *tRlogOutTask*, whenever a remote user is logged in. These processes exit when the remote connection is terminated.

**RETURNS** N/A

**SEE ALSO** *rlogLib*, *rlogInit()*, *iam()*

## *rlogInit()*

**NAME** *rlogInit()* – initialize the remote login facility

**SYNOPSIS** `STATUS rlogInit (void)`

**DESCRIPTION** This routine initializes the remote login facility. It creates a pty (pseudo tty) device and spawns *rlogind()*. If the configuration macro `INCLUDE_RLOGIN` is defined, *rlogInit()* is called automatically at boot time.

**RETURNS** OK or ERROR.

**SEE ALSO** *rlogLib*, *ptyDrv*

## *rm()*

**NAME** *rm()* – remove a file

**SYNOPSIS** `STATUS rm`  
`(`  
`char * fileName /* name of file to remove */`  
`)`

**DESCRIPTION** This command is provided for UNIX similarity. It simply calls *remove()*.

**RETURNS** OK, or ERROR if the file cannot be removed.

**SEE ALSO** *usrLib*, *remove()*, *VxWorks Programmer's Guide: Target Shell*

## *rmdir()*

|                    |                                                                                                                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>rmdir()</i> – remove a directory                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <pre>STATUS rmdir (     char * dirName /* name of directory to remove */ )</pre>                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>This command removes an existing directory from a hierarchical file system. The <i>dirName</i> string specifies the name of the directory to be removed, and may be either a full or relative pathname.</p> <p>This call is supported by the VxWorks NFS and dosFs file systems.</p> |
| <b>RETURNS</b>     | OK, or ERROR if the directory cannot be removed.                                                                                                                                                                                                                                        |
| <b>SEE ALSO</b>    | <i>usrLib</i> , <i>mkdir()</i> , <i>VxWorks Programmer's Guide: Target Shell</i>                                                                                                                                                                                                        |

---

## *rngBufGet()*

|                    |                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>rngBufGet()</i> – get characters from a ring buffer                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <pre>int rngBufGet (     RING_ID rngId, /* ring buffer to get data from */     char * buffer, /* pointer to buffer to receive data */     int maxbytes /* maximum number of bytes to get */ )</pre>                 |
| <b>DESCRIPTION</b> | <p>This routine copies bytes from the ring buffer <i>rngId</i> into <i>buffer</i>. It copies as many bytes as are available in the ring, up to <i>maxbytes</i>. The bytes copied will be removed from the ring.</p> |
| <b>RETURNS</b>     | The number of bytes actually received from the ring buffer; it may be zero if the ring buffer is empty at the time of the call.                                                                                     |
| <b>SEE ALSO</b>    | <i>rngLib</i>                                                                                                                                                                                                       |

---

## *rngBufPut()*

**NAME** *rngBufPut()* – put bytes into a ring buffer

**SYNOPSIS**

```
int rngBufPut
(
 RING_ID rngId, /* ring buffer to put data into */
 char * buffer, /* buffer to get data from */
 int nbytes /* number of bytes to try to put */
)
```

**DESCRIPTION** This routine puts bytes from *buffer* into ring buffer *ringId*. The specified number of bytes will be put into the ring, up to the number of bytes available in the ring.

**RETURNS** The number of bytes actually put into the ring buffer; it may be less than number requested, even zero, if there is insufficient room in the ring buffer at the time of the call.

**SEE ALSO** *rngLib*

---

## *rngCreate()*

**NAME** *rngCreate()* – create an empty ring buffer

**SYNOPSIS**

```
RING_ID rngCreate
(
 int nbytes /* number of bytes in ring buffer */
)
```

**DESCRIPTION** This routine creates a ring buffer of size *nbytes*, and initializes it. Memory for the buffer is allocated from the system memory partition.

**RETURNS** The ID of the ring buffer, or NULL if memory cannot be allocated.

**SEE ALSO** *rngLib*

## ***rngDelete()***

|                    |                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>rngDelete()</i> – delete a ring buffer                                                    |
| <b>SYNOPSIS</b>    | <pre>void rngDelete (     RING_ID ringId /* ring buffer to delete */ )</pre>                 |
| <b>DESCRIPTION</b> | This routine deletes a specified ring buffer. Any data currently in the buffer will be lost. |
| <b>RETURNS</b>     | N/A                                                                                          |
| <b>SEE ALSO</b>    | <b>rngLib</b>                                                                                |

---

## ***rngFlush()***

|                    |                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>rngFlush()</i> – make a ring buffer empty                                                                 |
| <b>SYNOPSIS</b>    | <pre>void rngFlush (     RING_ID ringId /* ring buffer to initialize */ )</pre>                              |
| <b>DESCRIPTION</b> | This routine initializes a specified ring buffer to be empty. Any data currently in the buffer will be lost. |
| <b>RETURNS</b>     | N/A                                                                                                          |
| <b>SEE ALSO</b>    | <b>rngLib</b>                                                                                                |

---

## *rngFreeBytes()*

|                    |                                                                                          |
|--------------------|------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>rngFreeBytes()</i> – determine the number of free bytes in a ring buffer              |
| <b>SYNOPSIS</b>    | <pre>int rngFreeBytes (     RING_ID ringId /* ring buffer to examine */ )</pre>          |
| <b>DESCRIPTION</b> | This routine determines the number of bytes currently unused in a specified ring buffer. |
| <b>RETURNS</b>     | The number of unused bytes in the ring buffer.                                           |
| <b>SEE ALSO</b>    | <i>rngLib</i>                                                                            |

---

## *rngIsEmpty()*

|                    |                                                                             |
|--------------------|-----------------------------------------------------------------------------|
| <b>NAME</b>        | <i>rngIsEmpty()</i> – test if a ring buffer is empty                        |
| <b>SYNOPSIS</b>    | <pre>BOOL rngIsEmpty (     RING_ID ringId /* ring buffer to test */ )</pre> |
| <b>DESCRIPTION</b> | This routine determines if a specified ring buffer is empty.                |
| <b>RETURNS</b>     | TRUE if empty, FALSE if not.                                                |
| <b>SEE ALSO</b>    | <i>rngLib</i>                                                               |

## ***rngIsFull()***

**NAME** *rngIsFull()* – test if a ring buffer is full (no more room)

**SYNOPSIS**

```
BOOL rngIsFull
(
 RING_ID ringId /* ring buffer to test */
)
```

**DESCRIPTION** This routine determines if a specified ring buffer is completely full.

**RETURNS** TRUE if full, FALSE if not.

**SEE ALSO** **rngLib**

---

## ***rngMoveAhead()***

**NAME** *rngMoveAhead()* – advance a ring pointer by *n* bytes

**SYNOPSIS**

```
void rngMoveAhead
(
 RING_ID ringId, /* ring buffer to be advanced */
 int n /* number of bytes ahead to move input pointer */
)
```

**DESCRIPTION** This routine advances the ring buffer input pointer by *n* bytes. This makes *n* bytes available in the ring buffer, after having been written ahead in the ring buffer with *rngPutAhead()*.

**RETURNS** N/A

**SEE ALSO** **rngLib**

---

## *rngNBytes()*

**NAME** *rngNBytes()* – determine the number of bytes in a ring buffer

**SYNOPSIS**

```
int rngNBytes
(
 RING_ID ringId /* ring buffer to be enumerated */
)
```

**DESCRIPTION** This routine determines the number of bytes currently in a specified ring buffer.

**RETURNS** The number of bytes filled in the ring buffer.

**SEE ALSO** **rngLib**

---

## *rngPutAhead()*

**NAME** *rngPutAhead()* – put a byte ahead in a ring buffer without moving ring pointers

**SYNOPSIS**

```
void rngPutAhead
(
 RING_ID ringId, /* ring buffer to put byte in */
 char byte, /* byte to be put in ring */
 int offset /* offset beyond next input byte where to put byte */
)
```

**DESCRIPTION** This routine writes a byte into the ring, but does not move the ring buffer pointers. Thus the byte will not yet be available to *rngBufGet()* calls. The byte is written *offset* bytes ahead of the next input location in the ring. Thus, an offset of 0 puts the byte in the same position as would **RNG\_ELEM\_PUT** would put a byte, except that the input pointer is not updated.

Bytes written ahead in the ring buffer with this routine can be made available all at once by subsequently moving the ring buffer pointers with the routine *rngMoveAhead()*.

Before calling *rngPutAhead()*, the caller must verify that at least *offset + 1* bytes are available in the ring buffer.

**RETURNS** N/A

**SEE ALSO** **rngLib**

## ***romStart()***

**NAME** *romStart()* – generic ROM initialization

**SYNOPSIS**

```
void romStart
(
 int startType /* start type */
)
```

**DESCRIPTION** This is the first C code executed after reset.

This routine is called by the assembly start-up code in *romInit()*. It clears memory, copies ROM to RAM, and possibly invokes the uncompressor. It then jumps to the entry point of the uncompressed object code.

**RETURNS** N/A

**SEE ALSO** *bootInit*

---

## ***round()***

**NAME** *round()* – round a number to the nearest integer

**SYNOPSIS**

```
double round
(
 double x /* value to round */
)
```

**DESCRIPTION** This routine rounds a double-precision value *x* to the nearest integral value.

**INCLUDE FILES** *math.h*

**RETURNS** The double-precision representation of *x* rounded to the nearest integral value.

**SEE ALSO** *mathALib*

---

## *roundf()*

|                      |                                                                                        |
|----------------------|----------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>roundf()</i> – round a number to the nearest integer                                |
| <b>SYNOPSIS</b>      | <pre>float roundf (     float x /* argument */ )</pre>                                 |
| <b>DESCRIPTION</b>   | This routine rounds a single-precision value <i>x</i> to the nearest integral value.   |
| <b>INCLUDE FILES</b> | <code>math.h</code>                                                                    |
| <b>RETURNS</b>       | The single-precision representation of <i>x</i> rounded to the nearest integral value. |
| <b>SEE ALSO</b>      | <code>mathALib</code>                                                                  |

---

## *routeAdd()*

|                    |                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>routeAdd()</i> – add a route                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <pre>STATUS routeAdd (     char * destination, /* inet addr or name of route destination */     char * gateway      /* inet addr or name of gateway to destination */ )</pre>                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>This routine adds gateways to the network routing tables. It is called from a VxWorks machine that needs to establish a gateway to a destination network (or machine).</p> <p>You can specify both <i>destination</i> and <i>gateway</i> in standard Internet address format (for example, 90.0.0.2), or you can specify them using their host names, as specified with <i>hostAdd()</i>.</p> |
| <b>EXAMPLE</b>     | <p>Consider the following example:</p> <pre>-&gt; routeAdd "90.0.0.0", "gate"</pre> <p>This call tells VxWorks that the machine with the host name "gate" is the gateway to network 90.0.0.0. The host "gate" must already have been created by <i>hostAdd()</i>.</p> <p>Consider the following example:</p>                                                                                     |

## ***routeDelete()***

```
-> routeAdd "90.0.0.0", "91.0.0.3"
```

This call tells VxWorks that the machine with the Internet address 91.0.0.3 is the gateway to network 90.0.0.0.

Consider the following example:

```
-> routeAdd "destination", "gate"
```

This call tells VxWorks that the machine with the host name "gate" is the gateway to the machine named "destination". The host names "gate" and "destination" must already have been created by *hostAdd()*.

Consider the following example:

```
-> routeAdd "0", "gate"
```

This call tells VxWorks that the machine with the host name "gate" is the default gateway. The host "gate" must already have been created by *hostAdd()*. A default gateway is where Internet Protocol (IP) datagrams are routed when there is no specific routing table entry available for the destination IP network or host.

**RETURNS** OK or ERROR.

**SEE ALSO** *routeLib*

---

## ***routeDelete()***

**NAME** *routeDelete()* – delete a route

**SYNOPSIS**

```
STATUS routeDelete
(
 char * destination, /* inet addr or name of route destination */
 char * gateway /* inet addr or name of gateway to destination */
)
```

**DESCRIPTION** This routine deletes a specified route from the network routing tables.

**RETURNS** OK or ERROR.

**SEE ALSO** *routeLib*, *routeAdd()*

## *routeNetAdd()*

|                    |                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>routeNetAdd()</i> – add a route to a destination that is a network                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <pre>STATUS routeNetAdd (     char * destination, /* inet addr or name of network destination */     char * gateway      /* inet addr or name of gateway to destination */ )</pre>                                                 |
| <b>DESCRIPTION</b> | This routine is equivalent to <i>routeAdd()</i> , except that the destination address is assumed to be a network. This is useful for adding a route to a sub-network that is not on the same overall network as the local network. |
| <b>RETURNS</b>     | OK or ERROR.                                                                                                                                                                                                                       |
| <b>SEE ALSO</b>    | <i>routeLib</i>                                                                                                                                                                                                                    |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>routeProtoPrioritySet()</i> – set the priority of routes added by the routing protocol                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <pre>STATUS routeProtoPrioritySet (     int proto, /* protocol no, from m2Lib.h */     int prio  /* priority, &gt;= 0 , &lt;= 200 */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>This routine assigns a priority to a routing protocol. A route generated by the <i>proto</i> protocol is added to the routing table only if a protocol of higher priority does not already have that route installed in the table. Use <i>proto</i> to identify the protocol. See <b>m2Lib.h</b> for a listing of valid values for <i>proto</i>. Use <i>prio</i> to specify the priority level you want to assign to <i>proto</i>. The <i>prio</i> parameter may be any integer value greater or equal to 0 and less than or equal to 200. The higher values indicate higher priority. If you do not want VxWorks to prioritize protocols, do not call this routine.</p> <p>Routes that are added with the <i>routeAdd()</i> or <i>mRouteAdd()</i> call are of type <b>M2_ipRouteProto_other</b>. These are static routes that are not affected by routing protocols such as RIP and OSPF. To change the priority of routes added in this way pass the value <b>M2_ipRoute_Proto_other</b> in the first argument of this routine.</p> |

**RETURNS** OK if priority set successfully else ERROR.

**SEE ALSO** **routeLib**

---

## *routeShow()*

**NAME** *routeShow()* – display host and network routing tables

**SYNOPSIS** `void routeShow (void)`

**DESCRIPTION** This routine displays the current routing information contained in the routing table.

**EXAMPLE**

```
-> routeShow
ROUTE NET TABLE
destination gateway flags Refcnt Use Interface

90.0.0.0 90.0.0.63 1 1 142 enp0

ROUTE HOST TABLE
destination gateway flags Refcnt Use Interface

127.0.0.1 127.0.0.1 5 0 82 lo0

```

The flags field represents a decimal value of the flags specified for a given route. The following is a list of currently available flag values:

- 0x1 – route is usable (that is, "up")
- 0x2 – destination is a gateway
- 0x4 – host specific routing entry
- 0x8 – host or net unreachable
- 0x10 – created dynamically (by redirect)
- 0x20 – modified dynamically (by redirect)
- 0x40 – message confirmed
- 0x80 – subnet mask present
- 0x100 – generate new routes on use
- 0x200 – external daemon resolves name
- 0x400 – generated by ARP
- 0x800 – manually added (static)
- 0x1000 – just discard packets (during updates)
- 0x2000 – modified by management protocol
- 0x4000 – protocol specific routing flag
- 0x8000 – protocol specific routing flag

In the above display example, the entry in the ROUTE NET TABLE has a flag value of 1, which indicates that this route is "up" and usable and network specific (the 0x4 bit is turned off). The entry in the ROUTE HOST TABLE has a flag value of 5 (0x1 OR'ed with 0x4), which indicates that this route is "up" and usable and host-specific.

**RETURNS** N/A

**SEE ALSO** `netShow`

---

## *routeStatShow()*

**NAME** `routeStatShow()` – display routing statistics

**SYNOPSIS** `void routeStatShow (void)`

**DESCRIPTION** This routine displays routing statistics.

**RETURNS** N/A

**SEE ALSO** `netShow`

---

## *rpcInit()*

**NAME** `rpcInit()` – initialize the RPC package

**SYNOPSIS** `STATUS rpcInit (void)`

**DESCRIPTION** This routine must be called before any task can use the RPC facility; it spawns the portmap daemon. It is called automatically if the configuration macro `INCLUDE_RPC` is defined.

**RETURNS** OK, or ERROR if the portmap daemon cannot be spawned.

**SEE ALSO** `rpcLib`

## *rpcTaskInit()*

|                    |                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>rpcTaskInit()</i> – initialize a task’s access to the RPC package                                  |
| <b>SYNOPSIS</b>    | <code>STATUS rpcTaskInit (void)</code>                                                                |
| <b>DESCRIPTION</b> | This routine must be called by a task before it makes any calls to other routines in the RPC package. |
| <b>RETURNS</b>     | OK, or ERROR if there is insufficient memory or the routine is unable to add a task delete hook.      |
| <b>SEE ALSO</b>    | <code>rpcLib</code>                                                                                   |

## *rresvport()*

|                    |                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>rresvport()</i> – open a socket with a privileged port bound to it                                                    |
| <b>SYNOPSIS</b>    | <pre>int rresvport (     int * alport /* port number to initially try */ )</pre>                                         |
| <b>DESCRIPTION</b> | This routine opens a socket with a privileged port bound to it. It is analogous to the UNIX routine <i>rresvport()</i> . |
| <b>RETURNS</b>     | A socket descriptor, or ERROR if either the socket cannot be opened or all ports are in use.                             |
| <b>SEE ALSO</b>    | <code>remLib</code> , UNIX BSD 4.3 manual entry for <i>rresvport()</i>                                                   |

---

## *rt11FsDateSet()*

|                 |                                                                                                |
|-----------------|------------------------------------------------------------------------------------------------|
| <b>NAME</b>     | <i>rt11FsDateSet()</i> – set the rt11Fs file system date                                       |
| <b>SYNOPSIS</b> | <pre>void rt11FsDateSet (     int year, /* year (72...03 (RT-11's days are numbered)) */</pre> |

```

int month, /* month (0, or 1...12) */
int day /* day (0, or 1...31) */
)

```

**DESCRIPTION** This routine sets the date for the *rt11Fs* file system, which remains in effect until changed. All files created are assigned this creation date.

To set a blank date, invoke the command:

```
rt11FsDateSet (72, 0, 0); /* a date outside RT-11's epoch */
```

**NOTE** No automatic incrementing of the date is performed; each new date must be set with a call to this routine.

**RETURNS** N/A

## *rt11FsDevInit()*

**NAME** *rt11FsDevInit()* – initialize the *rt11Fs* device descriptor

**SYNOPSIS**

```

RT_VOL_DESC *rt11FsDevInit
(
 char * devName, /* device name */
 BLK_DEV * pBlkDev, /* pointer to block device info */
 BOOL rt11Fmt, /* TRUE if RT-11 skew & interleave */
 int nEntries, /* no. of dir entries incl term entry */
 BOOL changeNoWarn /* TRUE if no disk change warning */
)

```

**DESCRIPTION** This routine initializes the device descriptor. The *pBlkDev* parameter is a pointer to an already-created **BLK\_DEV** device structure. This structure contains definitions for various aspects of the physical device format, as well as pointers to the sector read, sector write, *ioctl()*, status check, and reset functions for the device.

The *rt11Fmt* parameter is TRUE if the device is to be accessed using standard RT-11 skew and interleave.

The device directory will consist of one segment able to contain at least as many files as specified by *nEntries*. If *nEntries* is equal to **RT\_FILES\_FOR\_2\_BLOCK\_SEG**, strict RT-11 compatibility is maintained.

The *changeNoWarn* parameter is TRUE if the disk may be changed without announcing the change via *rt11FsReadyChange()*. Setting *changeNoWarn* to TRUE causes the disk to be

***rt11FsInit()***

regularly remounted, in case it has been changed. This results in a significant performance penalty.

- NOTE** An ERROR is returned if *rt11Fmt* is TRUE and the **bd\_blksPerTrack**(sectors per track) field in the **BLK\_DEV** structure is odd. This is because an odd number of sectors per track is incompatible with the RT-11 interleaving algorithm.
- RETURNS** A pointer to the volume descriptor (**RT\_VOL\_DESC**), or NULL if invalid device parameters were specified, or the routine runs out of memory.
- SEE ALSO** **rt11FsLib**

---

***rt11FsInit()***

- NAME** *rt11FsInit()* – prepare to use the rt11Fs library
- SYNOPSIS**
- ```
STATUS rt11FsInit
(
    int maxFiles /* max no. of simultaneously open rt11Fs files */
)
```
- DESCRIPTION**
- This routine initializes the rt11Fs library. It must be called exactly once, before any other routine in the library. The *maxFiles* parameter specifies the number of rt11Fs files that may be open at once. This routine initializes the necessary memory structures and semaphores.
- This routine is called automatically from the root task, *usrRoot()*, in *usrConfig.c* when the configuration macro **INCLUDE_RT11FS** is defined.
- RETURNS** OK, or ERROR if memory is insufficient.
- SEE ALSO** **rt11FsLib**

rt11FsMkfs()

NAME *rt11FsMkfs()* – initialize a device and create an rt11Fs file system

SYNOPSIS

```
RT_VOL_DESC *rt11FsMkfs
(
    char *    volName, /* volume name to use */
    BLK_DEV * pBlkDev  /* pointer to block device struct */
)
```

DESCRIPTION This routine provides a quick method of creating an rt11Fs file system on a device. It is used instead of the two-step procedure of calling *rt11FsDevInit()* followed by an *ioctl()* call with an FIODISKINIT function code.

This routine provides defaults for the rt11Fs parameters expected by *rt11FsDevInit()*. The directory size is set to RT_FILES_FOR_2_BLOCK_SEG(defined in *rt11FsLib.h*). No standard disk format is assumed; this allows the use of rt11Fs on block devices with an odd number of sectors per track. The *changeNoWarn* parameter is defined as FALSE, indicating that the disk will not be replaced without *rt11FsReadyChange()* being called first.

If different values are needed for any of these parameters, the routine *rt11FsDevInit()* must be used instead of this routine, followed by a request for disk initialization using the *ioctl()* function FIODISKINIT.

RETURNS A pointer to an rt11Fs volume descriptor (RT_VOL_DESC), or NULL if there is an error.

SEE ALSO *rt11FsLib*, *rt11FsDevInit()*

rt11FsModeChange()

NAME *rt11FsModeChange()* – modify the mode of an rt11Fs volume

SYNOPSIS

```
void rt11FsModeChange
(
    RT_VOL_DESC * vdptr, /* pointer to volume descriptor */
    int          newMode /* O_RDONLY, O_WRONLY, or O_RDWR (both) */
)
```

rt11FsReadyChange()

- DESCRIPTION** This routine sets the volume descriptor mode to *newMode*. It should be called whenever the read and write capabilities are determined, usually after a ready change. See the manual entry for *rt11FsReadyChange()*.
- The *rt11FsDevInit()* routine initially sets the mode to **O_RDWR**, (e.g., both **O_RDONLY** and **O_WRONLY**).
- RETURNS** N/A
- SEE ALSO** *rt11FsLib*, *rt11FsDevInit()*, *rt11FsReadyChange()*

rt11FsReadyChange()

- NAME** *rt11FsReadyChange()* – notify rt11Fs of a change in ready status
- SYNOPSIS**
- ```
void rt11FsReadyChange
(
 RT_VOL_DESC * vdptr /* pointer to device descriptor */
)
```
- DESCRIPTION** This routine sets the volume descriptor state to **RT\_VD\_READY\_CHANGED**. It should be called whenever a driver senses that a device has come on-line or gone off-line (e.g., a disk has been inserted or removed).
- RETURNS** N/A
- SEE ALSO** *rt11FsLib*

***s()***

- NAME** *s()* – single-step a task
- SYNOPSIS**
- ```
STATUS s
(
    int     taskNameOrId, /* task to step; 0 = use default */
    INSTR * addr,        /* address to step to; 0 = next instruction */
    INSTR * addr1        /* address for npc, 0 = next instruction */
)
```

- DESCRIPTION** This routine single-steps a task that is stopped at a breakpoint.
 To execute, enter:
 -> **s [task[,addr[,addr1]]]**
- If *task* is omitted or zero, the last task referenced is assumed. If *addr* is non-zero, then the program counter is changed to *addr*; if *addr1* is non-zero, the next program counter is changed to *addr1*, and the task is stepped.
- CAVEAT** When a task is continued, *s()* does not distinguish between a suspended task or a task suspended by the debugger. Therefore, its use should be restricted to only those tasks being debugged.
- NOTE** The next program counter, *addr1*, is currently supported only by SPARC.
- RETURNS** OK, or ERROR if the debugging package is not installed, the task cannot be found, or the task is not suspended.
- SEE ALSO** **dbgLib**, *VxWorks Programmer's Guide: Target Shell*, **windsh**, *Tornado User's Guide: Shell*

sa1100DevInit()

- NAME** *sa1100DevInit()* – initialise an SA1100 channel
- SYNOPSIS**
- ```
void sa1100DevInit
(
 SA1100_CHAN * pChan /* ptr to SA1100_CHAN describing this channel */
)
```
- DESCRIPTION** This routine initialises some **SIO\_CHAN** function pointers and then resets the chip to a quiescent state. Before this routine is called, the BSP must already have initialised all the device addresses, etc. in the **SA1100\_CHAN** structure.
- RETURNS** N/A
- SEE ALSO** **sa1100Sio**

## **saIoWrite()**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>saIoWrite()</i> – send a packet to the master agent's message queue                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <pre>STATUS saIoWrite (     PTR_T      ipchandle, /* Subagent's identifier */     EBUFFER_T * pBuf,    /* Encoded buffer */     INT_32_T   code      /* Message type */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b> | This routine is called either from <i>snmpSaHandlerAsync()</i> or from the registration routines. <i>ipchandle</i> contains an identifier to the sub agents's message queue except for the case when the message is a response to <b>IPC_AYT</b> . In this case, it contains the identifier to the local queue at the master agent. The <i>pBuf</i> parameter points to the message being sent. The <i>code</i> parameter takes a value that indicates how the master agent should process the message. Value <i>code</i> values are <b>CALL_QUERY_HANDLER</b> , <b>CALL_REG_HANDLER</b> , and <b>IPC_AYT</b> . For more on how these values influence message processing in the master agent, see the description of <i>snmpMonitorSpawn()</i> . |
| <b>RETURNS</b>     | OK or ERROR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SEE ALSO</b>    | <b>saIoLib</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

---

## **saIpcFree()**

**NAME** *saIpcFree()* – free the specified IPC mechanism

**SYNOPSIS**

```
void saIpcFree
(
 PTR_T ipchandle /* pointer to IPC handle */
)
```

**DESCRIPTION** Call this routine to free the IPC mechanism specified by *ipchandle*. You created this IPC mechanism with a call to *snmpSaInit()*. If you rewrote *snmpSaInit()* to use an IPC mechanism other than message queues, you must rewrite *saIpcFree()* to match.

**RETURNS** N/A

**SEE ALSO** *saIoLib*

---

## **saMsgBuild()**

**NAME** *saMsgBuild()* – build and encode a message and send it to the master agent

**SYNOPSIS**

```
void saMsgBuild
(
 VBL_T * vblast, /* pointer to varbind list */
 SA_HEADER_T * hdr_blk, /* pointer to header block */
 SA_DEMUX_T * demuxer, /* pointer to demuxer */
 PTR_T saId /* IPC handle */
)
```

**DESCRIPTION** The *hdrBlkCreate()* routine calls *saMsgBuild()* to build a message, encode it, and transmit it to the master agent. The message is built up from the information provided in the input parameters:

*vblast*

Expects a pointer to the **VBL\_T** structure containing the varbind list you want to include in the message.

*hdr\_blk*

Expects a pointer to the header for this message.

*demuxer*

Expects a pointer to the demuxer information for this message. The demuxer

**scanf()**

information consists of a string and an object ID. In a message dealing with a version 1 request, the string is the community string and the object ID is unused. In a message dealing with a version 2 request, the string is the local entity string from the context and the object ID is the local time object ID from the context.

*said*

Expects a pointer to the IPC mechanism (a message queue ID) that the master agent can use to respond to this message.

To encode the message, this routine calls *snmpSubEncode()*. To send the message to the master agent, this routine calls *saIoWrite()*.

**RETURNS** N/A

**SEE ALSO** **saIoLib**

**scanf()**

**NAME** *scanf()* – read and convert characters from the standard input stream (ANSI)

**SYNOPSIS**

```
int scanf
(
 char const * fmt /* format string */
)
```

**DESCRIPTION** This routine reads input from the standard input stream under the control of the string *fmt*. It is equivalent to *fscanf()* with an *fp* argument of **stdin**.

**INCLUDE FILES** **stdio.h**

**RETURNS** The number of input items assigned, which can be fewer than provided for, or even zero, in the event of an early matching failure; or EOF if an input failure occurs before any conversion.

**SEE ALSO** **ansiStdio**, *fscanf()*, *sscanf()*

---

## *sched\_get\_priority\_max()*

|                    |                                                                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>sched_get_priority_max()</i> – get the maximum priority (POSIX)                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <pre>int sched_get_priority_max (     int policy /* scheduling policy */ )</pre>                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | This routine returns the value of the highest possible task priority for a specified scheduling policy ( <b>SCHED_FIFO</b> or <b>SCHED_RR</b> ).                                                                                                                                                                               |
| <b>NOTE</b>        | If the global variable <b>posixPriorityNumbering</b> is <b>FALSE</b> , the VxWorks native priority numbering scheme is used, in which higher priorities are indicated by smaller numbers. This is different than the priority numbering scheme specified by POSIX, in which higher priorities are indicated by larger numbers. |
| <b>RETURNS</b>     | Maximum priority value, or -1 (ERROR) on error.                                                                                                                                                                                                                                                                                |
| <b>ERRNO</b>       | <b>EINVAL</b><br>– invalid scheduling policy.                                                                                                                                                                                                                                                                                  |
| <b>SEE ALSO</b>    | <b>schedPxBLib</b>                                                                                                                                                                                                                                                                                                             |

## *sched\_getscheduler()*

**NAME** *sched\_getscheduler()* – get the current scheduling policy (POSIX)

**SYNOPSIS**

```
int sched_getscheduler
(
 pid_t tid /* task ID */
)
```

**DESCRIPTION** This routine returns the current scheduling policy (i.e., SCHED\_FIFO or SCHED\_RR).

**RETURNS** Current scheduling policy (SCHED\_FIFO or SCHED\_RR), or -1 (ERROR) on error.

**ERRNO** ESRCH  
– invalid task ID.

**SEE ALSO** schedPxBLib

---

## *sched\_rr\_get\_interval()*

**NAME** *sched\_rr\_get\_interval()* – get the current time slice (POSIX)

**SYNOPSIS**

```
int sched_rr_get_interval
(
 pid_t tid, /* task ID */
 struct timespec * interval /* struct to store time slice */
)
```

**DESCRIPTION** This routine sets *interval* to the current time slice period if round-robin scheduling is currently enabled.

**RETURNS** 0 (OK) if successful, -1 (ERROR) on error.

**ERRNO** EINVAL  
– round-robin scheduling is not currently enabled.  
ESRCH  
– invalid task ID.

**SEE ALSO** schedPxBLib

---

## ***sched\_setparam()***

**NAME** *sched\_setparam()* – set a task’s priority (POSIX)

**SYNOPSIS**

```
int sched_setparam
(
 pid_t tid, /* task ID */
 const struct sched_param * param /* scheduling parameter */
)
```

**DESCRIPTION** This routine sets the priority of a specified task, *tid*. If *tid* is 0, it sets the priority of the calling task. Valid priority numbers are 0 through 255.

The *param* argument is a structure whose member **sched\_priority** is the integer priority value. For example, the following program fragment sets the calling task’s priority to 13 using POSIX interfaces:

```
#include "sched.h"
...
struct sched_param AppSchedPrio;
...
AppSchedPrio.sched_priority = 13;
if (sched_setparam (0, &AppSchedPrio) != OK)
{
 ... /* recovery attempt or abort message */
}
...
```

**NOTE** If the global variable **posixPriorityNumbering** is FALSE, the VxWorks native priority numbering scheme is used, in which higher priorities are indicated by smaller numbers. This is different than the priority numbering scheme specified by POSIX, in which higher priorities are indicated by larger numbers.

**RETURNS** 0 (OK) if successful, or -1 (ERROR) on error.

**ERRNO**

- EINVAL**  
– scheduling priority is outside valid range.
- ESRCH**  
– task ID is invalid.

**SEE ALSO** **schedPxLib**

| <b>NAME</b>        | <i>sched_setscheduler()</i> – set scheduling policy and scheduling parameters (POSIX)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <pre>int sched_setscheduler (     pid_t          tid,    /* task ID */     int            policy, /* scheduling policy requested */     const struct sched_param * param /* scheduling parameters requested */ )</pre>                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>This routine sets the scheduling policy and scheduling parameters for a specified task, <i>tid</i>. If <i>tid</i> is 0, it sets the scheduling policy and scheduling parameters for the calling task.</p> <p>Because VxWorks does not set scheduling policies (e.g., round-robin scheduling) on a task-by-task basis, setting a scheduling policy that conflicts with the current system policy simply fails and <i>errno</i> is set to <b>EINVAL</b>. If the requested scheduling policy is the same as the current system policy, then this routine acts just like <i>sched_setparam()</i>.</p> |
| <b>NOTE</b>        | <p>If the global variable <b>posixPriorityNumbering</b> is <b>FALSE</b>, the VxWorks native priority numbering scheme is used, in which higher priorities are indicated by smaller numbers. This is different than the priority numbering scheme specified by POSIX, in which higher priorities are indicated by larger numbers.</p>                                                                                                                                                                                                                                                                 |
| <b>RETURNS</b>     | The previous scheduling policy ( <b>SCHED_FIFO</b> or <b>SCHED_RR</b> ), or -1 ( <b>ERROR</b> ) on error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>ERRNO</b>       | <b>EINVAL</b><br>– scheduling priority is outside valid range, or it is impossible to set the specified scheduling policy.<br><b>ESRCH</b><br>– invalid task ID.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SEE ALSO</b>    | <i>schedPxBLib</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## *sched\_yield()*

|                    |                                                          |
|--------------------|----------------------------------------------------------|
| <b>NAME</b>        | <i>sched_yield()</i> – relinquish the CPU (POSIX)        |
| <b>SYNOPSIS</b>    | <pre>int sched_yield (void)</pre>                        |
| <b>DESCRIPTION</b> | This routine forces the running task to give up the CPU. |

***scsi2IfInit()***

**RETURNS** 0 (OK) if successful, or -1 (ERROR) on error.

**SEE ALSO** **schedPxLib**

***scsi2IfInit()***

**NAME** *scsi2IfInit()* – initialize the SCSI-2 interface to scsiLib

**SYNOPSIS** `void scsi2IfInit ()`

**DESCRIPTION** This routine initializes the SCSI-2 function interface by adding all the routines in **scsi2Lib** plus those in **scsiDirectLib** and **scsiCommonLib**. It is invoked by **usrConfig.c** if the macro **INCLUDE\_SCSI2** is defined in **config.h**. The calling interface remains the same between SCSI-1 and SCSI-2; this routine simply sets the calling interface function pointers to the SCSI-2 functions.

**RETURNS** N/A

**SEE ALSO** **scsi2Lib**

***scsiAutoConfig()***

**NAME** *scsiAutoConfig()* – configure all devices connected to a SCSI controller

**SYNOPSIS** `STATUS scsiAutoConfig  
(  
    SCSI_CTRL * pScsiCtrl /* ptr to SCSI controller info */  
)`

**DESCRIPTION** This routine cycles through all valid SCSI bus IDs and logical unit numbers (LUNs), attempting a *scsiPhysDevCreate()* with default parameters on each. All devices which support the INQUIRY command are configured. The *scsiShow()* routine can be used to find the system table of SCSI physical devices attached to a specified SCSI controller. In addition, *scsiPhysDevIdGet()* can be used programmatically to get a pointer to the **SCSI\_PHYS\_DEV** structure associated with the device at a specified SCSI bus ID and LUN.

**RETURNS** OK, or ERROR if *pScsiCtrl* and the global variable **pSysScsiCtrl** are both NULL.

**SEE ALSO** **scsiLib**

---

## *scsiBlkDevCreate()*

- NAME** *scsiBlkDevCreate()* – define a logical partition on a SCSI block device
- SYNOPSIS**
- ```
BLK_DEV * scsiBlkDevCreate
(
    SCSI_PHYS_DEV * pScsiPhysDev, /* ptr to SCSI physical device info */
    int             numBlocks,    /* number of blocks in block device */
    int             blockOffset  /* address of first block in volume */
)
```
- DESCRIPTION** This routine creates and initializes a **BLK_DEV** structure, which describes a logical partition on a SCSI physical-block device. A logical partition is an array of contiguously addressed blocks; it can be completely described by the number of blocks and the address of the first block in the partition. In normal configurations partitions do not overlap, although such a condition is not an error.
- NOTE** If *numBlocks* is 0, the rest of device is used.
- RETURNS** A pointer to the created **BLK_DEV**, or NULL if parameters exceed physical device boundaries, if the physical device is not a block device, or if memory is insufficient for the structures.
- SEE ALSO** *scsiLib*

scsiBlkDevInit()

- NAME** *scsiBlkDevInit()* – initialize fields in a SCSI logical partition
- SYNOPSIS**
- ```
void scsiBlkDevInit
(
 SCSI_BLK_DEV * pScsiBlkDev, /* ptr to SCSI block dev. struct */
 int blksPerTrack, /* blocks per track */
 int nHeads /* number of heads */
)
```
- DESCRIPTION** This routine specifies the disk-geometry parameters required by certain file systems (for example, dosFs). It is called after a **SCSI\_BLK\_DEV** structure is created with *scsiBlkDevCreate()*, but before calling a file system initialization routine. It is generally required only for removable-media devices.

***scsiBlkDevShow()***

**RETURNS** N/A

**SEE ALSO** **scsiLib**

---

***scsiBlkDevShow()***

**NAME** *scsiBlkDevShow()* – show the BLK\_DEV structures on a specified physical device

**SYNOPSIS**

```
void scsiBlkDevShow
(
 SCSI_PHYS_DEV * pScsiPhysDev /* ptr to SCSI physical device info */
)
```

**DESCRIPTION** This routine displays all of the BLK\_DEV structures created on a specified physical device. This routine is called by *scsiShow()* but may also be invoked directly, usually from the shell.

**RETURNS** N/A

**SEE ALSO** **scsiLib**, *scsiShow()*

---

***scsiBusReset()***

**NAME** *scsiBusReset()* – pulse the reset signal on the SCSI bus

**SYNOPSIS**

```
STATUS scsiBusReset
(
 SCSI_CTRL * pScsiCtrl /* ptr to SCSI controller info */
)
```

**DESCRIPTION** This routine calls a controller-specific routine to reset a specified controller's SCSI bus. If no controller is specified (*pScsiCtrl* is 0), the value in the global variable **pSysScsiCtrl** is used.

**RETURNS** OK, or ERROR if there is no controller or controller-specific routine.

**SEE ALSO** **scsiLib**

---

## *scsiCacheSnoopDisable()*

**NAME** *scsiCacheSnoopDisable()* – inform SCSI that hardware snooping of caches is disabled

**SYNOPSIS**

```
void scsiCacheSnoopDisable
(
 SCSI_CTRL * pScsiCtrl /* pointer to a SCSI_CTRL structure */
)
```

**DESCRIPTION** This routine informs the SCSI library that hardware snooping is disabled and that **scsi2Lib** should execute any necessary cache coherency code. In order to make **scsi2Lib** aware that hardware snooping is disabled, this routine should be called after all SCSI-2 initializations, especially after *scsi2CtrlInit()*.

**RETURNS** N/A

**SEE ALSO** **scsi2Lib**

---

## *scsiCacheSnoopEnable()*

**NAME** *scsiCacheSnoopEnable()* – inform SCSI that hardware snooping of caches is enabled

**SYNOPSIS**

```
void scsiCacheSnoopEnable
(
 SCSI_CTRL * pScsiCtrl /* pointer to a SCSI_CTRL structure */
)
```

**DESCRIPTION** This routine informs the SCSI library that hardware snooping is enabled and that **scsi2Lib** need not execute any cache coherency code. In order to make **scsi2Lib** aware that hardware snooping is enabled, this routine should be called after all SCSI-2 initializations, especially after *scsi2CtrlInit()*.

**RETURNS** N/A

**SEE ALSO** **scsi2Lib**

**scsiCacheSynchronize()**

---

**scsiCacheSynchronize()**

**NAME** *scsiCacheSynchronize()* – synchronize the caches for data coherency

**SYNOPSIS**

```
void scsiCacheSynchronize
(
 SCSI_THREAD * pThread, /* ptr to thread info */
 SCSI_CACHE_ACTION action /* cache action required */
)
```

**DESCRIPTION** This routine performs whatever cache action is necessary to ensure cache coherency with respect to the various buffers involved in a SCSI command.

The process is as follows:

1. The buffers for command, identification, and write data, which are simply written to SCSI, are flushed before the command.
2. The status buffer, which is written and then read, is cleared (flushed and invalidated) before the command.
3. The data buffer for a read command, which is only read, is cleared before the command.

The data buffer for a read command is cleared before the command rather than invalidated after it because it may share dirty cache lines with data outside the read buffer. DMA drivers for older versions of the SCSI library have flushed the first and last bytes of the data buffer before the command. However, this approach is not sufficient with the enhanced SCSI library because the amount of data transferred into the buffer may not fill it, which would cause dirty cache lines which contain correct data for the un-filled part of the buffer to be lost when the buffer is invalidated after the command.

To optimize the performance of the driver in supporting different caching policies, the routine uses the `CACHE_USER_FLUSH` macro when flushing the cache. In the absence of a `CACHE_USER_CLEAR` macro, the following steps are taken:

1. If there is a non-NULL flush routine in the `cacheUserFuncs` structure, the cache is cleared.
2. If there is a non-NULL invalidate routine, the cache is invalidated.
3. Otherwise nothing is done; the cache is assumed to be coherent without any software intervention.

Finally, since flushing (clearing) cache line entries for a large data buffer can be time-consuming, if the data buffer is larger than a preset (run-time configurable) size, the entire cache is flushed.

**RETURNS** N/A

SEE ALSO *scsi2Lib*

---

## *scsiErase()*

**NAME** *scsiErase()* – issue an ERASE command to a SCSI device

**SYNOPSIS**

```
STATUS scsiErase
(
 SCSI_PHYS_DEV * pScsiPhysDev, /* ptr to SCSI physical device */
 BOOL longErase /* TRUE for entire tape erase */
)
```

**DESCRIPTION** This routine issues an ERASE command to a specified SCSI device.

**RETURNS** OK, or ERROR if the command fails.

**SEE ALSO** *scsiSeqLib*

---

## *scsiFormatUnit()*

**NAME** *scsiFormatUnit()* – issue a FORMAT\_UNIT command to a SCSI device

**SYNOPSIS**

```
STATUS scsiFormatUnit
(
 SCSI_PHYS_DEV * pScsiPhysDev, /* ptr to SCSI physical device */
 BOOL cmpDefectList, /* whether defect list is complete */
 int defListFormat, /* defect list format */
 int vendorUnique, /* vendor unique byte */
 int interleave, /* interleave factor */
 char * buffer, /* ptr to input data buffer */
 int bufLength /* length of buffer in bytes */
)
```

**DESCRIPTION** This routine issues a FORMAT\_UNIT command to a specified SCSI device.

**RETURNS** OK, or ERROR if the command fails.

**SEE ALSO** *scsiLib*

---

## ***scsiIdentMsgBuild()***

**NAME** *scsiIdentMsgBuild()* – build an identification message

**SYNOPSIS**

```
int scsiIdentMsgBuild
(
 UINT8 * msg,
 SCSI_PHYS_DEV * pScsiPhysDev,
 SCSI_TAG_TYPE tagType,
 UINT tagNumber
)
```

**DESCRIPTION** This routine builds an identification message in the caller's buffer, based on the specified physical device, tag type, and tag number.

If the target device does not support messages, there is no identification message to build.

Otherwise, the identification message consists of an IDENTIFY byte plus an optional QUEUE TAG message (two bytes), depending on the type of tag used.

**NOTE** This function is not intended for use by application programs.

**RETURNS** The length of the resulting identification message in bytes or -1 for ERROR.

**SEE ALSO** *scsi2Lib*

---

## ***scsiIdentMsgParse()***

**NAME** *scsiIdentMsgParse()* – parse an identification message

**SYNOPSIS**

```
SCSI_IDENT_STATUS scsiIdentMsgParse
(
 SCSI_CTRL * pScsiCtrl,
 UINT8 * msg,
 int msgLength,
 SCSI_PHYS_DEV * * ppScsiPhysDev,
 SCSI_TAG * pTagNum
)
```

**DESCRIPTION** This routine scans a (possibly incomplete) identification message, validating it in the process. If there is an IDENTIFY message, it identifies the corresponding physical device.

If the physical device is currently processing an untagged (ITL) nexus, identification is complete. Otherwise, the identification is complete only if there is a complete QUEUE TAG message.

If there is no physical device corresponding to the IDENTIFY message, or if the device is processing tagged (ITLQ) nexuses and the tag does not correspond to an active thread (it may have been aborted by a timeout, for example), then the identification sequence fails.

The caller's buffers for physical device and tag number (the results of the identification process) are always updated. This is required by the thread event handler (see *scsiMgrThreadEvent()*.)

**NOTE** This function is not intended for use by application programs.

**RETURNS** The identification status (incomplete, complete, or rejected).

**SEE ALSO** `scsi2Lib`

---

## ***scsiInquiry()***

**NAME** *scsiInquiry()* – issue an INQUIRY command to a SCSI device

**SYNOPSIS**

```
STATUS scsiInquiry
(
 SCSI_PHYS_DEV * pScsiPhysDev, /* ptr to SCSI physical device */
 char * buffer, /* ptr to input data buffer */
 int bufLength /* length of buffer in bytes */
)
```

**DESCRIPTION** This routine issues an INQUIRY command to a specified SCSI device.

**RETURNS** OK, or ERROR if the command fails.

**SEE ALSO** `scsiLib`

***scsiIoctl()***

---

***scsiIoctl()***

**NAME** *scsiIoctl()* – perform a device-specific I/O control function

**SYNOPSIS**

```
STATUS scsiIoctl
(
 SCSI_PHYS_DEV * pScsiPhysDev, /* ptr to SCSI block device info */
 int function, /* function code */
 int arg /* argument to pass called function */
)
```

**DESCRIPTION** This routine performs a specified **ioctl** function using a specified SCSI block device.

**RETURNS** The status of the request, or ERROR if the request is unsupported.

**SEE ALSO** *scsiLib*

---

***scsiLoadUnit()***

**NAME** *scsiLoadUnit()* – issue a LOAD/UNLOAD command to a SCSI device

**SYNOPSIS**

```
STATUS scsiLoadUnit
(
 SCSI_SEQ_DEV * pScsiSeqDev, /* ptr to SCSI physical device */
 BOOL load, /* TRUE=load, FALSE=unload */
 BOOL reten, /* TRUE=retention and unload */
 BOOL eot /* TRUE=end of tape and unload */
)
```

**DESCRIPTION** This routine issues a LOAD/UNLOAD command to a specified SCSI device.

**RETURNS** OK, or ERROR if the command fails.

**SEE ALSO** *scsiSeqLib*

---

## *scsiMgrBusReset()*

|                    |                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>scsiMgrBusReset()</i> – handle a controller-bus reset event                                                                                                                     |
| <b>SYNOPSIS</b>    | <pre>void scsiMgrBusReset (     SCSI_CTRL * pScsiCtrl /* SCSI ctrlr on which bus reset */ )</pre>                                                                                  |
| <b>DESCRIPTION</b> | This routine resets in turn: each attached physical device, each target, and the controller-finite-state machine. In practice, this routine implements the SCSI hard reset option. |
| <b>NOTE</b>        | This routine does not physically reset the SCSI bus; see <i>scsiBusReset()</i> . This routine should not be called by application programs.                                        |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                |
| <b>SEE ALSO</b>    | <i>scsiMgrLib</i>                                                                                                                                                                  |

---

## *scsiMgrCtrlEvent()*

|                    |                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>scsiMgrCtrlEvent()</i> – send an event to the SCSI controller state machine                                                                                                                        |
| <b>SYNOPSIS</b>    | <pre>void scsiMgrCtrlEvent (     SCSI_CTRL *      pScsiCtrl,     SCSI_EVENT_TYPE eventType )</pre>                                                                                                    |
| <b>DESCRIPTION</b> | This routine is called by the thread driver whenever selection, reselection, or disconnection occurs or when a thread is activated. It manages a simple finite-state machine for the SCSI controller. |
| <b>NOTE</b>        | This function should not be called by application programs.                                                                                                                                           |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                   |
| <b>SEE ALSO</b>    | <i>scsiMgrLib</i>                                                                                                                                                                                     |

## ***scsiMgrEventNotify()***

- NAME** *scsiMgrEventNotify()* – notify the SCSI manager of a SCSI (controller) event
- SYNOPSIS**
- ```
STATUS scsiMgrEventNotify
(
    SCSI_CTRL * pScsiCtrl, /* pointer to SCSI controller structure */
    SCSI_EVENT * pEvent,   /* pointer to the SCSI event */
    int         eventSize /* size of the event information */
)
```
- DESCRIPTION** This routine posts an event message on the appropriate SCSI manager queue, then notifies the SCSI manager that there is a message to be accepted.
- NOTE** This routine should not be called by application programs.
No access serialization is required, because event messages are only posted by the SCSI controller ISR. See the reference entry for *scsiBusResetNotify()*.
- RETURNS** OK, or ERROR if the SCSI manager's event queue is full.
- SEE ALSO** *scsiMgrLib*, *scsiBusResetNotify()*
-

scsiMgrShow()

- NAME** *scsiMgrShow()* – show status information for the SCSI manager
- SYNOPSIS**
- ```
void scsiMgrShow
(
 SCSI_CTRL * pScsiCtrl, /* SCSI controller to use */
 BOOL showPhysDevs, /* TRUE => show phys dev details */
 BOOL showThreads, /* TRUE => show thread details */
 BOOL showFreeThreads /* TRUE => show free thread IDs */
)
```
- DESCRIPTION** This routine shows the current state of the SCSI manager for the specified controller, including the total number of threads created and the number of threads currently free.  
Optionally, this routine also shows details for all created physical devices on this controller and all threads for which SCSI requests are outstanding. It also shows the IDs of all free threads.

- NOTE** The information displayed is volatile; this routine is best used when there is no activity on the SCSI bus. Threads allocated by a client but for which there are no outstanding SCSI requests are not shown.
- RETURNS** N/A
- SEE ALSO** *scsiMgrLib*

---

## *scsiMgrThreadEvent()*

- NAME** *scsiMgrThreadEvent()* – send an event to the thread state machine
- SYNOPSIS**
- ```
void scsiMgrThreadEvent
(
    SCSI_THREAD *      pThread,
    SCSI_THREAD_EVENT_TYPE eventType
)
```
- DESCRIPTION** This routine forwards an event to the thread’s physical device. If the event is completion or deferral, it frees up the tag which was allocated when the thread was activated and either completes or defers the thread.
- NOTE** This function should not be called by application programs.
- The thread passed into this function does not have to be an active client thread (it may be an identification thread).
- If the thread has no corresponding physical device, this routine does nothing. (This occasionally occurs if an unexpected disconnection or bus reset happens when an identification thread has not yet identified which physical device it corresponds to.
- RETURNS** N/A
- SEE ALSO** *scsiMgrLib*

scsiModeSelect()

NAME *scsiModeSelect()* – issue a MODE_SELECT command to a SCSI device

SYNOPSIS

```
STATUS scsiModeSelect
(
    SCSI_PHYS_DEV * pScsiPhysDev, /* ptr to SCSI physical device */
    int            pageFormat,    /* value of the page format bit (0-1) */
    int            saveParams,    /* value of the save parameters bit (0-1) */
    char *        buffer,        /* ptr to output data buffer */
    int            bufLength      /* length of buffer in bytes */
)
```

DESCRIPTION This routine issues a MODE_SELECT command to a specified SCSI device.

RETURNS OK, or ERROR if the command fails.

SEE ALSO *scsiLib*

scsiModeSense()

NAME *scsiModeSense()* – issue a MODE_SENSE command to a SCSI device

SYNOPSIS

```
STATUS scsiModeSense
(
    SCSI_PHYS_DEV * pScsiPhysDev, /* ptr to SCSI physical device */
    int            pageControl,    /* value of the page control field (0-3) */
    int            pageCode,      /* value of the page code field (0-0x3f) */
    char *        buffer,        /* ptr to input data buffer */
    int            bufLength      /* length of buffer in bytes */
)
```

DESCRIPTION This routine issues a MODE_SENSE command to a specified SCSI device.

RETURNS OK, or ERROR if the command fails.

SEE ALSO *scsiLib*

scsiMsgInComplete()

NAME *scsiMsgInComplete()* – handle a complete SCSI message received from the target

SYNOPSIS

```
STATUS scsiMsgInComplete
(
    SCSI_CTRL * pScsiCtrl, /* ptr to SCSI controller info */
    SCSI_THREAD * pThread /* ptr to thread info */
)
```

DESCRIPTION This routine parses the complete message and takes any necessary action, which may include setting up an outgoing message in reply. If the message is not understood, the routine rejects it and returns an ERROR status.

NOTE This function is intended for use only by SCSI controller drivers.

RETURNS OK, or ERROR if the message is not supported.

SEE ALSO *scsi2Lib*

scsiMsgOutComplete()

NAME *scsiMsgOutComplete()* – perform post-processing after a SCSI message is sent

SYNOPSIS

```
STATUS scsiMsgOutComplete
(
    SCSI_CTRL * pScsiCtrl, /* ptr to SCSI controller info */
    SCSI_THREAD * pThread /* ptr to thread info */
)
```

DESCRIPTION This routine parses the complete message and takes any necessary action.

NOTE This function is intended for use only by SCSI controller drivers.

RETURNS OK, or ERROR if the message is not supported.

SEE ALSO *scsi2Lib*

scsiMsgOutReject()

NAME *scsiMsgOutReject()* – perform post-processing when an outgoing message is rejected

SYNOPSIS

```
void scsiMsgOutReject
(
    SCSI_CTRL * pScsiCtrl, /* ptr to SCSI controller info */
    SCSI_THREAD * pThread /* ptr to thread info */
)
```

DESCRIPTIONNOTE This function is intended for use only by SCSI controller drivers.

RETURNS OK, or ERROR if the message is not supported.

SEE ALSO *scsi2Lib*

scsiPhysDevCreate()

NAME *scsiPhysDevCreate()* – create a SCSI physical device structure

SYNOPSIS

```
SCSI_PHYS_DEV * scsiPhysDevCreate
(
    SCSI_CTRL * pScsiCtrl, /* ptr to SCSI controller info */
    int devBusId,          /* device's SCSI bus ID */
    int devLUN,            /* device's logical unit number */
    int reqSenseLength,    /* length of REQUEST SENSE data dev returns */
    int devType,           /* type of SCSI device */
    BOOL removable,        /* whether medium is removable */
    int numBlocks,         /* number of blocks on device */
    int blockSize          /* size of a block in bytes */
)
```

DESCRIPTION This routine enables access to a SCSI device and must be the first routine invoked. It must be called once for each physical device on the SCSI bus.

If *reqSenseLength* is NULL (0), one or more **REQUEST_SENSE** commands are issued to the device to determine the number of bytes of sense data it typically returns. Note that if the device returns variable amounts of sense data depending on its state, you must consult the device manual to determine the maximum amount of sense data that can be returned.

If *devType* is NONE (-1), an INQUIRY command is issued to determine the device type; as an added benefit, it acquires the device's make and model number. The *scsiShow()* routine displays this information. Common values of *devType* can be found in *scsiLib.h* or in the SCSI specification.

If *numBlocks* or *blockSize* are specified as NULL (0), a READ_CAPACITY command is issued to determine those values. This occurs only for device types supporting READ_CAPACITY.

RETURNS A pointer to the created SCSI_PHYS_DEV structure, or NULL if the routine is unable to create the physical-device structure.

SEE ALSO *scsiLib*

scsiPhysDevDelete()

NAME *scsiPhysDevDelete()* – delete a SCSI physical-device structure

SYNOPSIS

```
STATUS scsiPhysDevDelete
(
    SCSI_PHYS_DEV * pScsiPhysDev /* ptr to SCSI physical device info */
)
```

DESCRIPTION This routine deletes a specified SCSI physical-device structure.

RETURNS OK, or ERROR if *pScsiPhysDev* is NULL or SCSI_BLK_DEVS have been created on the device.

SEE ALSO *scsiLib*

scsiPhysDevIdGet()

NAME *scsiPhysDevIdGet()* – return a pointer to a SCSI_PHYS_DEV structure

SYNOPSIS

```
SCSI_PHYS_DEV * scsiPhysDevIdGet
(
    SCSI_CTRL * pScsiCtrl, /* ptr to SCSI controller info */
    int        devBusId,  /* device's SCSI bus ID */
    int        devLUN     /* device's logical unit number */
)
```

scsiPhysDevShow()

| | |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | This routine returns a pointer to the <code>SCSI_PHYS_DEV</code> structure of the SCSI physical device located at a specified bus ID (<i>devBusId</i>) and logical unit number (<i>devLUN</i>) and attached to a specified SCSI controller (<i>pScsiCtrl</i>). |
| RETURNS | A pointer to the <code>SCSI_PHYS_DEV</code> structure, or <code>NULL</code> if the structure does not exist. |
| SEE ALSO | <code>scsiLib</code> |

scsiPhysDevShow()

NAME `scsiPhysDevShow()` – show status information for a physical device

SYNOPSIS

```
void scsiPhysDevShow
(
    SCSI_PHYS_DEV * pScsiPhysDev, /* physical device to be displayed */
    BOOL          showThreads, /* show IDs of associated threads */
    BOOL          noHeader     /* do not print title line */
)
```

DESCRIPTION This routine shows the state, the current nexus type, the current tag number, the number of tagged commands in progress, and the number of waiting and active threads for a SCSI physical device. Optionally, it shows the IDs of waiting and active threads, if any. This routine may be called at any time, but note that all of the information displayed is volatile.

RETURNS N/A

SEE ALSO `scsi2Lib`

scsiRdSecs()

NAME `scsiRdSecs()` – read sector(s) from a SCSI block device

SYNOPSIS

```
STATUS scsiRdSecs
(
    SCSI_BLK_DEV * pScsiBlkDev, /* ptr to SCSI block device info */
    int          sector, /* sector number to be read */
    int          numSecs, /* total sectors to be read */
    char *      buffer /* ptr to input data buffer */
)
```

DESCRIPTION This routine reads the specified physical sector(s) from a specified physical device.

RETURNS OK, or ERROR if the sector(s) cannot be read.

SEE ALSO `scsiLib`

scsiRdTape()

NAME `scsiRdTape()` – read bytes or blocks from a SCSI tape device

SYNOPSIS

```
int scsiRdTape
(
    SCSI_SEQ_DEV * pScsiSeqDev, /* ptr to SCSI sequential device info */
    UINT          count,        /* total bytes or blocks to be read */
    char *        buffer,       /* ptr to input data buffer */
    BOOL          fixedSize     /* if variable size blocks */
)
```

DESCRIPTION This routine reads the specified number of bytes or blocks from a specified physical device. If the boolean *fixedSize* is true, then *numBytes* represents the number of blocks of size *blockSize*, defined in the `pScsiPhysDev` structure. If variable block sizes are used (*fixedSize* = FALSE), then *numBytes* represents the actual number of bytes to be read.

RETURNS Number of bytes or blocks actually read, 0 if EOF, or ERROR.

SEE ALSO `scsiSeqLib`

scsiReadCapacity()

NAME `scsiReadCapacity()` – issue a READ_CAPACITY command to a SCSI device

SYNOPSIS

```
STATUS scsiReadCapacity
(
    SCSI_PHYS_DEV * pScsiPhysDev, /* ptr to SCSI physical device */
    int *          pLastLBA,      /* where to return last logical block */
    int *          pBlkLength     /* where to return block length */
)
```

DESCRIPTION This routine issues a READ_CAPACITY command to a specified SCSI device.

RETURNS OK, or ERROR if the command fails.

SEE ALSO **scsiLib**

scsiRelease()

NAME *scsiRelease()* – issue a RELEASE command to a SCSI device

SYNOPSIS

```
STATUS scsiRelease
(
    SCSI_PHYS_DEV * pScsiPhysDev /* ptr to SCSI physical device */
)
```

DESCRIPTION This routine issues a RELEASE command to a specified SCSI device.

RETURNS OK, or ERROR if the command fails.

SEE ALSO **scsiDirectLib**

scsiReleaseUnit()

NAME *scsiReleaseUnit()* – issue a RELEASE UNIT command to a SCSI device

SYNOPSIS

```
STATUS scsiReleaseUnit
(
    SCSI_SEQ_DEV * pScsiSeqDev /* ptr to SCSI sequential device */
)
```

DESCRIPTION This routine issues a RELEASE UNIT command to a specified SCSI device.

RETURNS OK, or ERROR if the command fails.

SEE ALSO **scsiSeqLib**

scsiReqSense()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>scsiReqSense()</i> – issue a REQUEST_SENSE command to a SCSI device and read results |
| SYNOPSIS | <pre>STATUS scsiReqSense (SCSI_PHYS_DEV * pScsiPhysDev, /* ptr to SCSI physical device */ char * buffer, /* ptr to input data buffer */ int bufLength /* length of buffer in bytes */)</pre> |
| DESCRIPTION | This routine issues a REQUEST_SENSE command to a specified SCSI device and reads the results. |
| RETURNS | OK, or ERROR if the command fails. |
| SEE ALSO | <i>scsiLib</i> |

scsiReserve()

| | |
|--------------------|------------------------------------------------------------------------------------------------------|
| NAME | <i>scsiReserve()</i> – issue a RESERVE command to a SCSI device |
| SYNOPSIS | <pre>STATUS scsiReserve (SCSI_PHYS_DEV * pScsiPhysDev /* ptr to SCSI physical device */)</pre> |
| DESCRIPTION | This routine issues a RESERVE command to a specified SCSI device. |
| RETURNS | OK, or ERROR if the command fails. |
| SEE ALSO | <i>scsiDirectLib</i> |

scsiReserveUnit()

NAME *scsiReserveUnit()* – issue a RESERVE UNIT command to a SCSI device

SYNOPSIS

```
STATUS scsiReserveUnit
(
    SCSI_SEQ_DEV * pScsiSeqDev /* ptr to SCSI sequential device */
)
```

DESCRIPTION This routine issues a RESERVE UNIT command to a specified SCSI device.

RETURNS OK, or ERROR if the command fails.

SEE ALSO *scsiSeqLib*

scsiRewind()

NAME *scsiRewind()* – issue a REWIND command to a SCSI device

SYNOPSIS

```
STATUS scsiRewind
(
    SCSI_SEQ_DEV * pScsiSeqDev /* ptr to SCSI Sequential device */
)
```

DESCRIPTION This routine issues a REWIND command to a specified SCSI device.

RETURNS OK, or ERROR if the command fails.

SEE ALSO *scsiSeqLib*

scsiSeqDevCreate()

NAME *scsiSeqDevCreate()* – create a SCSI sequential device

SYNOPSIS

```
SEQ_DEV *scsiSeqDevCreate
(
    SCSI_PHYS_DEV * pScsiPhysDev /* ptr to SCSI physical device info */
)
```

DESCRIPTION This routine creates a SCSI sequential device and saves a pointer to this SEQ_DEV in the SCSI physical device. The following functions are initialized in this structure:

| | |
|---------------------------------|-------------------------------------------------------|
| <code>sd_seqRd</code> | – <code>scsiRdTape()</code> |
| <code>sd_seqWrt</code> | – <code>scsiWrtTape()</code> |
| <code>sd_ioctl</code> | – <code>scsiIoctl()</code> (in <code>scsiLib</code>) |
| <code>sd_seqWrtFileMarks</code> | – <code>scsiWrtFileMarks()</code> |
| <code>sd_statusChk</code> | – <code>scsiSeqStatusCheck()</code> |
| <code>sd_reset</code> | – (not used) |
| <code>sd_rewind</code> | – <code>scsiRewind()</code> |
| <code>sd_reserve</code> | – <code>scsiReserve()</code> |
| <code>sd_release</code> | – <code>scsiRelease()</code> |
| <code>sd_readBlkLim</code> | – <code>scsiSeqReadBlockLimits()</code> |
| <code>sd_load</code> | – <code>scsiLoadUnit()</code> |
| <code>sd_space</code> | – <code>scsiSpace()</code> |
| <code>sd_erase</code> | – <code>scsiErase()</code> |

Only one SEQ_DEV per SCSI_PHYS_DEV is allowed, unlike BLK_DEVS where an entire list is maintained. Therefore, this routine can be called only once per creation of a sequential device.

RETURNS A pointer to the SEQ_DEV structure, or NULL if the command fails.

SEE ALSO `scsiSeqLib`

scsiSeqIoctl()

scsiSeqIoctl()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>scsiSeqIoctl()</i> – perform an I/O control function for sequential access devices |
| SYNOPSIS | <pre>int scsiSeqIoctl (SCSI_SEQ_DEV * pScsiSeqDev, /* ptr to SCSI sequential device */ int function, /* ioctl function code */ int arg /* argument to pass to called function */)</pre> |
| DESCRIPTION | This routine issues scsiSeqLib commands to perform sequential device-specific I/O control operations. |
| RETURNS | OK or ERROR. |
| ERRNO | S_scsiLib_INVALID_BLOCK_SIZE |
| SEE ALSO | scsiSeqLib |

scsiSeqReadBlockLimits()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>scsiSeqReadBlockLimits()</i> – issue a READ_BLOCK_LIMITS command to a SCSI device |
| SYNOPSIS | <pre>STATUS scsiSeqReadBlockLimits (SCSI_SEQ_DEV * pScsiSeqDev, /* ptr to SCSI sequential device */ int * pMaxBlockLength, /* where to return max block length */ UINT16 * pMinBlockLength /* where to return min block length */)</pre> |
| DESCRIPTION | This routine issues a READ_BLOCK_LIMITS command to a specified SCSI device. |
| RETURNS | OK, or ERROR if the command fails. |
| SEE ALSO | scsiSeqLib |

scsiSeqStatusCheck()

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>scsiSeqStatusCheck()</i> – detect a change in media |
| SYNOPSIS | <pre>STATUS scsiSeqStatusCheck (SCSI_SEQ_DEV * pScsiSeqDev /* ptr to a sequential dev */)</pre> |
| DESCRIPTION | This routine issues a TEST_UNIT_READY command to a SCSI device to detect a change in media. It is called by file systems before executing <i>open()</i> or <i>creat()</i> . |
| RETURNS | OK or ERROR. |
| SEE ALSO | <i>scsiSeqLib</i> |

scsiShow()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>scsiShow()</i> – list the physical devices attached to a SCSI controller |
| SYNOPSIS | <pre>STATUS scsiShow (SCSI_CTRL * pScsiCtrl /* ptr to SCSI controller info */)</pre> |
| DESCRIPTION | This routine displays the SCSI bus ID, logical unit number (LUN), vendor ID, product ID, firmware revision (rev.), device type, number of blocks, block size in bytes, and a pointer to the associated SCSI_PHYS_DEV structure for each physical SCSI device known to be attached to a specified SCSI controller. |
| NOTE | If <i>pScsiCtrl</i> is NULL, the value of the global variable pSysScsiCtrl is used, unless it is also NULL. |
| RETURNS | OK, or ERROR if both <i>pScsiCtrl</i> and pSysScsiCtrl are NULL. |
| SEE ALSO | <i>scsiLib</i> |

scsiSpace()

scsiSpace()**NAME** *scsiSpace()* – move the tape on a specified physical SCSI device

SYNOPSIS

```

STATUS scsiSpace
(
    SCSI_SEQ_DEV * pScsiSeqDev, /* ptr to SCSI sequential device info */
    int          count,         /* count for space command */
    int          spaceCode     /* code for the type of space command */
)

```

DESCRIPTION This routine moves the tape on a specified SCSI physical device. There are two types of space code that are mandatory in SCSI; currently these are the only two supported:

| Code | Description | Support |
|------|-----------------------|---------|
| 000 | Blocks | Yes |
| 001 | File marks | Yes |
| 010 | Sequential file marks | No |
| 011 | End-of-data | No |
| 100 | Set marks | No |
| 101 | Sequential set marks | No |

RETURNS OK, or ERROR if an error is returned by the device.

ERRNO S_scsiLib_ILLEGAL_REQUEST

SEE ALSO *scsiSeqLib*

scsiStartStopUnit()

NAME *scsiStartStopUnit()* – issue a START_STOP_UNIT command to a SCSI device

SYNOPSIS

```

STATUS scsiStartStopUnit
(
    SCSI_PHYS_DEV * pScsiPhysDev, /* ptr to SCSI physical device */
    BOOL          start           /* TRUE == start, FALSE == stop */
)

```

DESCRIPTION This routine issues a START_STOP_UNIT command to a specified SCSI device.

RETURNS OK, or ERROR if the command fails.

SEE ALSO *scsiDirectLib*

2

scsiSyncXferNegotiate()

NAME *scsiSyncXferNegotiate()* – initiate or continue negotiating transfer parameters

SYNOPSIS

```
void scsiSyncXferNegotiate
(
    SCSI_CTRL *          pScsiCtrl, /* ptr to SCSI controller info */
    SCSI_TARGET *       pScsiTarget, /* ptr to SCSI target info */
    SCSI_SYNC_XFER_EVENT eventType /* tells what has just happened */
)
```

DESCRIPTION This routine manages negotiation by means of a finite-state machine which is driven by "significant events" such as incoming and outgoing messages. Each SCSI target has its own independent state machine.

NOTE If the controller does not support synchronous transfer or if the target's maximum REQ/ACK offset is zero, attempts to initiate a round of negotiation are ignored. This function is intended for use only by SCSI controller drivers.

RETURNS N/A

SEE ALSO *scsi2Lib*

scsiTapeModeSelect()

NAME *scsiTapeModeSelect()* – issue a MODE_SELECT command to a SCSI tape device

SYNOPSIS

```
STATUS scsiTapeModeSelect
(
    SCSI_PHYS_DEV *pScsiPhysDev, /* ptr to SCSI physical device */
    int pageFormat,             /* value of the page format bit (0-1) */
    int saveParams,            /* value of the save parameters bit (0-1) */
    char *buffer,              /* ptr to output data buffer */
    int bufLength              /* length of buffer in bytes */
)
```

scsiTapeModeSense()

DESCRIPTION This routine issues a **MODE_SELECT** command to a specified SCSI device.

RETURNS OK, or ERROR if the command fails.

SEE ALSO `scsiSeqLib`

scsiTapeModeSense()

NAME `scsiTapeModeSense()` – issue a **MODE_SENSE** command to a SCSI tape device

SYNOPSIS

```
STATUS scsiTapeModeSense
(
    SCSI_PHYS_DEV *pScsiPhysDev, /* ptr to SCSI physical device */
    int pageControl,             /* value of the page control field (0-3) */
    int pageCode,               /* value of the page code field (0-0x3f) */
    char *buffer,               /* ptr to input data buffer */
    int bufLength               /* length of buffer in bytes */
)
```

DESCRIPTION This routine issues a **MODE_SENSE** command to a specified SCSI tape device.

RETURNS OK, or ERROR if the command fails.

SEE ALSO `scsiSeqLib`

scsiTargetOptionsGet()

NAME `scsiTargetOptionsGet()` – get options for one or all SCSI targets

SYNOPSIS

```
STATUS scsiTargetOptionsGet
(
    SCSI_CTRL * pScsiCtrl, /* ptr to SCSI controller info */
    int devBusId, /* target to interrogate */
    SCSI_OPTIONS * pOptions /* buffer to return options */
)
```

DESCRIPTION This routine copies the current options for the specified target into the caller's buffer.

RETURNS OK, or ERROR if the bus ID is invalid.

SEE ALSO *scsi2Lib*

scsiTargetOptionsSet()

NAME *scsiTargetOptionsSet()* – set options for one or all SCSI targets

SYNOPSIS

```
STATUS scsiTargetOptionsSet
(
    SCSI_CTRL *   pScsiCtrl, /* ptr to SCSI controller info */
    int           devBusId, /* target to affect, or all */
    SCSI_OPTIONS * pOptions, /* buffer containing new options */
    UINT          which     /* which options to change */
)
```

DESCRIPTION This routine sets the options defined by the bitmask **which** for the specified target (or all targets if **devBusId** is `SCSI_SET_OPT_ALL_TARGETS`).

The bitmask **which** can be any combination of the following, bitwise OR'd together (corresponding fields in the `SCSI_OPTIONS` structure are shown in parentheses):

| | | |
|---------------------------------------|---------------------------------------|------------------------------------------------------------------------|
| <code>SCSI_SET_OPT_TIMEOUT</code> | selTimeOut | select timeout period, microseconds |
| <code>SCSI_SET_OPT_MESSAGES</code> | messages | FALSE to disable SCSI messages |
| <code>SCSI_SET_OPT_DISCONNECT</code> | disconnect | FALSE to disable discon/recon |
| <code>SCSI_SET_OPT_XFER_PARAMS</code> | maxOffset, minPeriod | max sync xfer offset, 0>async min sync xfer period, x 4 nsec. |
| <code>SCSI_SET_OPT_TAG_PARAMS</code> | tagType, maxTags | default tag type (<code>SCSI_TAG_*</code>) max cmd tags available |
| <code>SCSI_SET_OPT_WIDE_PARAMS</code> | xferWidth | data transfer width in bits |

NOTE This routine can be used after the target device has already been used; in this case, however, it is not possible to change the tag parameters. This routine must not be used while there is any SCSI activity on the specified target(s).

RETURNS OK, or ERROR if the bus ID or options are invalid.

SEE ALSO *scsi2Lib*

scsiTestUnitRdy()

scsiTestUnitRdy()

NAME *scsiTestUnitRdy()* – issue a TEST_UNIT_READY command to a SCSI device

SYNOPSIS `STATUS scsiTestUnitRdy`
`(`
`SCSI_PHYS_DEV * pScsiPhysDev /* ptr to SCSI physical device */`
`)`

DESCRIPTION This routine issues a TEST_UNIT_READY command to a specified SCSI device.

RETURNS OK, or ERROR if the command fails.

SEE ALSO `scsiLib`

scsiThreadInit()

NAME *scsiThreadInit()* – perform generic SCSI thread initialization

SYNOPSIS `STATUS scsiThreadInit`
`(`
`SCSI_THREAD * pThread`
`)`

DESCRIPTION This routine initializes the controller-independent parts of a thread structure, which are specific to the SCSI manager.

NOTE This function should not be called by application programs. It is intended to be used by SCSI controller drivers.

RETURNS OK, or ERROR if the thread cannot be initialized.

SEE ALSO `scsi2Lib`

scsiWideXferNegotiate()

NAME *scsiWideXferNegotiate()* – initiate or continue negotiating wide parameters

SYNOPSIS

```
void scsiWideXferNegotiate
(
    SCSI_CTRL *          pScsiCtrl, /* ptr to SCSI controller info */
    SCSI_TARGET *       pScsiTarget, /* ptr to SCSI target info */
    SCSI_WIDE_XFER_EVENT eventType /* tells what has just happened */
)
```

DESCRIPTION This routine manages negotiation means of a finite-state machine which is driven by "significant events" such as incoming and outgoing messages. Each SCSI target has its own independent state machine.

NOTE If the controller does not support wide transfers or the target's transfer width is zero, attempts to initiate a round of negotiation are ignored; this is because zero is the default narrow transfer.

This function is intended for use only by SCSI controller drivers.

RETURNS N/A

SEE ALSO *scsi2Lib*

scsiWrtFileMarks()

NAME *scsiWrtFileMarks()* – write file marks to a SCSI sequential device

SYNOPSIS

```
STATUS scsiWrtFileMarks
(
    SCSI_SEQ_DEV * pScsiSeqDev, /* ptr to SCSI sequential device info */
    int           numMarks, /* number of file marks to write */
    BOOL          shortMark /* TRUE to write short file mark */
)
```

DESCRIPTION This routine writes file marks to a specified physical device.

RETURNS OK, or ERROR if the file mark cannot be written.

SEE ALSO *scsiSeqLib*

scsiWrtSecs()

scsiWrtSecs()

NAME `scsiWrtSecs()` – write sector(s) to a SCSI block device

SYNOPSIS

```
STATUS scsiWrtSecs
(
    SCSI_BLK_DEV * pScsiBlkDev, /* ptr to SCSI block device info */
    int          sector,        /* sector number to be written */
    int          numSecs,       /* total sectors to be written */
    char *       buffer         /* ptr to input data buffer */
)
```

DESCRIPTION This routine writes the specified physical sector(s) to a specified physical device.

RETURNS OK, or ERROR if the sector(s) cannot be written.

SEE ALSO `scsiLib`

scsiWrtTape()

NAME `scsiWrtTape()` – write data to a SCSI tape device

SYNOPSIS

```
STATUS scsiWrtTape
(
    SCSI_SEQ_DEV * pScsiSeqDev, /* ptr to SCSI sequential device info */
    int          numBytes,      /* total bytes or blocks to be written */
    char *       buffer,        /* ptr to input data buffer */
    BOOL         fixedSize     /* if variable size blocks */
)
```

DESCRIPTION This routine writes data to the current block on a specified physical device. If the boolean *fixedSize* is true, then *numBytes* represents the number of blocks of size *blockSize*, defined in the `pScsiPhysDev` structure. If variable block sizes are used (*fixedSize* = FALSE), then *numBytes* represents the actual number of bytes to be written. If *numBytes* is greater than the `maxBytesLimit` field defined in the `pScsiPhysDev` structure, then more than one SCSI transaction is used to transfer the data.

RETURNS OK, or ERROR if the data cannot be written or zero bytes are written.

SEE ALSO `scsiSeqLib`

select()

NAME *select()* – pend on a set of file descriptors

SYNOPSIS

```
int select
(
    int          width,      /* number of bits to examine from 0 */
    fd_set *    pReadFds,   /* read fds */
    fd_set *    pWriteFds,  /* write fds */
    fd_set *    pExceptFds, /* exception fds (unsupported) */
    struct timeval * pTimeout /* max time to wait, NULL = forever */
)
```

DESCRIPTION This routine permits a task to pend until one of a set of file descriptors becomes ready. Three parameters -- *pReadFds*, *pWriteFds*, and *pExceptFds* -- point to file descriptor sets in which each bit corresponds to a particular file descriptor. Bits set in the read file descriptor set (*pReadFds*) will cause *select()* to pend until data is available on any of the corresponding file descriptors, while bits set in the write file descriptor set (*pWriteFds*) will cause *select()* to pend until any of the corresponding file descriptors become writable. (The *pExceptFds* parameter is currently unused, but is provided for UNIX call compatibility.)

The following macros are available for setting the appropriate bits in the file descriptor set structure:

```
FD_SET(fd, &fdset)
FD_CLR(fd, &fdset)
FD_ZERO(&fdset)
```

If either *pReadFds* or *pWriteFds* is NULL, they are ignored. The *width* parameter defines how many bits will be examined in the file descriptor sets, and should be set to either the maximum file descriptor value in use plus one, or simply to `FD_SETSIZE`. When *select()* returns, it zeros out the file descriptor sets, and sets only the bits that correspond to file descriptors that are ready. The `FD_ISSET` macro may be used to determine which bits are set.

If *pTimeout* is NULL, *select()* will block indefinitely. If *pTimeout* is not NULL, but points to a `timeval` structure with an effective time of zero, the file descriptors in the file descriptor sets will be polled and the results returned immediately. If the effective time value is greater than zero, *select()* will return after the specified time has elapsed, even if none of the file descriptors are ready.

Applications can use *select()* with pipes and serial devices, in addition to sockets. Also, *select()* now examines write file descriptors in addition to read file descriptors; however, exception file descriptors remain unsupported.

selectInit()

Driver developers should consult the *VxWorks Programmer's Guide: I/O System* for details on writing drivers that will use *select()*.

RETURNS The number of file descriptors with activity, 0 if timed out, or ERROR if an error occurred when the driver's *select()* routine was invoked via *ioctl()*.

SEE ALSO *selectLib*, *VxWorks Programmer's Guide: I/O System*

selectInit()

NAME *selectInit()* – initialize the select facility

SYNOPSIS `void selectInit (void)`

DESCRIPTION This routine initializes the UNIX BSD 4.3 select facility. It should be called only once, and typically is called from the root task, *usrRoot()*, in *usrConfig.c*. It installs a task delete hook that cleans up after a task if the task is deleted while pending in *select()*.

RETURNS N/A

SEE ALSO *selectLib*

selNodeAdd()

NAME *selNodeAdd()* – add a wake-up node to a *select()* wake-up list

SYNOPSIS `STATUS selNodeAdd
(
 SEL_WAKEUP_LIST * pWakeupList, /* list of tasks to wake up */
 SEL_WAKEUP_NODE * pWakeupNode /* node to add to list */
)`

DESCRIPTION This routine adds a wake-up node to a device's wake-up list. It is typically called from a driver's FIOSELECT function.

RETURNS OK, or ERROR if memory is insufficient.

SEE ALSO *selectLib*

selNodeDelete()

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>selNodeDelete()</i> – find and delete a node from a <i>select()</i> wake-up list |
| SYNOPSIS | <pre>STATUS selNodeDelete (SEL_WAKEUP_LIST * pWakeupList, /* list of tasks to wake up */ SEL_WAKEUP_NODE * pWakeupNode /* node to delete from list */)</pre> |
| DESCRIPTION | This routine deletes a specified wake-up node from a specified wake-up list. Typically, it is called by a driver's FIOUNSELECT function. |
| RETURNS | OK, or ERROR if the node is not found in the wake-up list. |
| SEE ALSO | <i>selectLib</i> |

selWakeup()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>selWakeup()</i> – wake up a task pending in <i>select()</i> |
| SYNOPSIS | <pre>void selWakeup (SEL_WAKEUP_NODE * pWakeupNode /* node to wake up */)</pre> |
| DESCRIPTION | This routine wakes up a task pending in <i>select()</i> . Once a driver's FIOSELECT function installs a wake-up node in a device's wake-up list (using <i>selNodeAdd()</i>) and checks to make sure the device is ready, this routine ensures that the <i>select()</i> call does not pend. |
| RETURNS | N/A |
| SEE ALSO | <i>selectLib</i> |

selWakeupAll()

selWakeupAll()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>selWakeupAll()</i> – wake up all tasks in a <i>select()</i> wake-up list |
| SYNOPSIS | <pre>void selWakeupAll (SEL_WAKEUP_LIST * pWakeupList, /* list of tasks to wake up */ SELECT_TYPE type /* readers (SELREAD) or writers (SELWRITE) */)</pre> |
| DESCRIPTION | This routine wakes up all tasks pending in <i>select()</i> that are waiting for a device; it is called by a driver when the device becomes ready. The <i>type</i> parameter specifies the task to be awakened, either reader tasks (SELREAD) or writer tasks (SELWRITE). |
| RETURNS | N/A |
| SEE ALSO | <i>selectLib</i> |

selWakeupListInit()

| | |
|--------------------|----------------------------------------------------------------------------------------------------------|
| NAME | <i>selWakeupListInit()</i> – initialize a <i>select()</i> wake-up list |
| SYNOPSIS | <pre>void selWakeupListInit (SEL_WAKEUP_LIST * pWakeupList /* wake-up list to initialize */)</pre> |
| DESCRIPTION | This routine should be called in a device's create routine to initialize the SEL_WAKEUP_LIST structure. |
| RETURNS | N/A |
| SEE ALSO | <i>selectLib</i> |

selWakeupListLen()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>selWakeupListLen()</i> – get the number of nodes in a <i>select()</i> wake-up list |
| SYNOPSIS | <pre>int selWakeupListLen (SEL_WAKEUP_LIST * pWakeupList /* list of tasks to wake up */)</pre> |
| DESCRIPTION | This routine returns the number of nodes in a specified <code>SEL_WAKEUP_LIST</code> . It can be used by a driver to determine if any tasks are currently pending in <i>select()</i> on this device, and whether these tasks need to be activated with <i>selWakeupAll()</i> . |
| RETURNS | The number of nodes currently in a <i>select()</i> wake-up list, or <code>ERROR</code> . |
| SEE ALSO | <code>selectLib</code> |

selWakeupType()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>selWakeupType()</i> – get the type of a <i>select()</i> wake-up node |
| SYNOPSIS | <pre>SELECT_TYPE selWakeupType (SEL_WAKEUP_NODE * pWakeupNode /* node to get type of */)</pre> |
| DESCRIPTION | This routine returns the type of a specified <code>SEL_WAKEUP_NODE</code> . It is typically used in a device's <code>FIOSELECT</code> function to determine if the device is being selected for read or write operations. |
| RETURNS | <code>SELREAD</code> (read operation) or <code>SELWRITE</code> (write operation). |
| SEE ALSO | <code>selectLib</code> |

semBCreate()

semBCreate()

NAME `semBCreate()` – create and initialize a binary semaphore

SYNOPSIS

```
SEM_ID semBCreate
(
    int          options,      /* semaphore options */
    SEM_B_STATE initialState /* initial semaphore state */
)
```

DESCRIPTION This routine allocates and initializes a binary semaphore. The semaphore is initialized to the *initialState* of either `SEM_FULL` (1) or `SEM_EMPTY` (0).

The *options* parameter specifies the queuing style for blocked tasks. Tasks can be queued on a priority basis or a first-in-first-out basis. These options are `SEM_Q_PRIORITY` (0x1) and `SEM_Q_FIFO` (0x0), respectively.

RETURNS The semaphore ID, or NULL if memory cannot be allocated.

SEE ALSO `semBLib`

semBSmCreate()

NAME `semBSmCreate()` – create and initialize a shared memory binary semaphore (VxMP Opt.)

SYNOPSIS

```
SEM_ID semBSmCreate
(
    int          options,      /* semaphore options */
    SEM_B_STATE initialState /* initial semaphore state */
)
```

DESCRIPTION This routine allocates and initializes a shared memory binary semaphore. The semaphore is initialized to an *initialState* of either `SEM_FULL` (available) or `SEM_EMPTY` (not available). The shared semaphore structure is allocated from the shared semaphore dedicated memory partition.

The semaphore ID returned by this routine can be used directly by the generic semaphore-handling routines in `semLib` -- `semGive()`, `semTake()`, and `semFlush()` -- and the show routines, such as `show()` and `semShow()`.

The queuing style for blocked tasks is set by *options*; the only supported queuing style for shared memory semaphores is first-in-first-out, selected by `SEM_Q_FIFO`.

Before this routine can be called, the shared memory objects facility must be initialized (see **semSmLib**).

The maximum number of shared memory semaphores (binary plus counting) that can be created is **SM_OBJ_MAX_SEM**.

| | |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| AVAILABILITY | This routine is distributed as a component of the unbundled shared memory support option, VxMP. |
| RETURNS | The semaphore ID, or NULL if memory cannot be allocated from the shared semaphore dedicated memory partition. |
| ERRNO | S_memLib_NOT_ENOUGH_MEMORY , S_semLib_INVALID_QUEUE_TYPE , S_semLib_INVALID_STATE , S_smObjLib_LOCK_TIMEOUT |
| SEE ALSO | semSmLib , semLib , semBLib , smObjLib , semShow |

semCCreate()

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>semCCreate()</i> – create and initialize a counting semaphore |
| SYNOPSIS | <pre>SEM_ID semCCreate (int options, /* semaphore option modes */ int initialCount /* initial count */)</pre> |
| DESCRIPTION | <p>This routine allocates and initializes a counting semaphore. The semaphore is initialized to the specified initial count.</p> <p>The <i>options</i> parameter specifies the queuing style for blocked tasks. Tasks may be queued on a priority basis or a first-in-first-out basis. These options are SEM_Q_PRIORITY (0x1) and SEM_Q_FIFO (0x0), respectively.</p> |
| RETURNS | The semaphore ID, or NULL if memory cannot be allocated. |
| SEE ALSO | semCLib |

semClear()

NAME *semClear()* – take a release 4.x semaphore, if the semaphore is available

SYNOPSIS

```
STATUS semClear
(
    SEM_ID semId /* semaphore ID to empty */
)
```

DESCRIPTION This routine takes a VxWorks 4.x semaphore if it is available (full), otherwise no action is taken except to return ERROR. This routine never preempts the caller.

RETURNS OK, or ERROR if the semaphore is unavailable.

SEE ALSO semOLib

semCreate()

NAME *semCreate()* – create and initialize a release 4.x binary semaphore

SYNOPSIS

```
SEM_ID semCreate (void)
```

DESCRIPTION This routine allocates a VxWorks 4.x binary semaphore. The semaphore is initialized to empty. After initialization, it must be given before it can be taken.

RETURNS The semaphore ID, or NULL if memory cannot be allocated.

SEE ALSO semOLib, *semInit()*

semCSmCreate()

NAME *semCSmCreate()* – create and initialize a shared memory counting semaphore (VxMP Opt.)

SYNOPSIS

```
SEM_ID semCSmCreate
(
    int options,      /* semaphore options */
    int initialCount /* initial semaphore count */
)
```

| | |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | <p>This routine allocates and initializes a shared memory counting semaphore. The initial count value of the semaphore (the number of times the semaphore should be taken before it can be given) is specified by <i>initialCount</i>.</p> <p>The semaphore ID returned by this routine can be used directly by the generic semaphore-handling routines in semLib -- <i>semGive()</i>, <i>semTake()</i> and <i>semFlush()</i> -- and the show routines, such as <i>show()</i> and <i>semShow()</i>.</p> <p>The queuing style for blocked tasks is set by <i>options</i>; the only supported queuing style for shared memory semaphores is first-in-first-out, selected by SEM_Q_FIFO.</p> <p>Before this routine can be called, the shared memory objects facility must be initialized (see semSmLib).</p> <p>The maximum number of shared memory semaphores (binary plus counting) that can be created is SM_OBJ_MAX_SEM.</p> |
| AVAILABILITY | This routine is distributed as a component of the unbundled shared memory support option, VxMP. |
| RETURNS | The semaphore ID, or NULL if memory cannot be allocated from the shared semaphore dedicated memory partition. |
| ERRNO | S_memLib_NOT_ENOUGH_MEMORY , S_semLib_INVALID_QUEUE_TYPE , S_smObjLib_LOCK_TIMEOUT |
| SEE ALSO | semSmLib , semLib , semCLib , smObjLib , semShow |

semDelete()

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>semDelete()</i> – delete a semaphore |
| SYNOPSIS | <pre>STATUS semDelete (SEM_ID semId /* semaphore ID to delete */)</pre> |
| DESCRIPTION | This routine terminates and deallocates any memory associated with a specified semaphore. Any pending tasks will unblock and return ERROR. |
| WARNING | Take care when deleting semaphores, particularly those used for mutual exclusion, to avoid deleting a semaphore out from under a task that already has taken (owns) that semaphore. Applications should adopt the protocol of only deleting semaphores that the deleting task has successfully taken. |

semFlush()

- RETURNS** OK, or ERROR if the semaphore ID is invalid.
- ERRNO** S_intLib_NOT_ISR_CALLABLE, S_objLib_OBJ_ID_ERROR, S_smObjLib_NO_OBJECT_DESTROY
- SEE ALSO** semLib, semBLib, semCLib, semMLib, semSmLib

semFlush()

- NAME** *semFlush()* – unblock every task pended on a semaphore
- SYNOPSIS**
- ```
STATUS semFlush
(
 SEM_ID semId /* semaphore ID to unblock everyone for */
)
```
- DESCRIPTION**
- This routine atomically unblocks all tasks pended on a specified semaphore, i.e., all tasks will be unblocked before any is allowed to run. The state of the underlying semaphore is unchanged. All pended tasks will enter the ready queue before having a chance to execute.
- The flush operation is useful as a means of broadcast in synchronization applications. Its use is illegal for mutual-exclusion semaphores created with *semMCreate()*.
- RETURNS** OK, or ERROR if the semaphore ID is invalid or the operation is not supported.
- ERRNO** S\_objLib\_OBJ\_ID\_ERROR
- SEE ALSO** semLib, semBLib, semCLib, semMLib, semSmLib

---

## ***semGive()***

- NAME** *semGive()* – give a semaphore
- SYNOPSIS**
- ```
STATUS semGive
(
    SEM_ID semId /* semaphore ID to give */
)
```

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | This routine performs the give operation on a specified semaphore. Depending on the type of semaphore, the state of the semaphore and of the pending tasks may be affected. The behavior of <i>semGive()</i> is discussed fully in the library description of the specific semaphore type being used. |
| RETURNS | OK, or ERROR if the semaphore ID is invalid. |
| ERRNO | S_intLib_NOT_ISR_CALLABLE, S_objLib_OBJ_ID_ERROR, S_semLib_INVALID_OPERATION |
| SEE ALSO | semLib, semBLib, semCLib, semMLib, semSmLib |

semInfo()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>semInfo()</i> – get a list of task IDs that are blocked on a semaphore |
| SYNOPSIS | <pre>int semInfo (SEM_ID semId, /* semaphore ID to summarize */ int idList[], /* array of task IDs to be filled in */ int maxTasks /* max tasks idList can accommodate */)</pre> |
| DESCRIPTION | This routine reports the tasks blocked on a specified semaphore. Up to <i>maxTasks</i> task IDs are copied to the array specified by <i>idList</i> . The array is unordered. |
| WARNING | There is no guarantee that all listed tasks are still valid or that new tasks have not been blocked by the time <i>semInfo()</i> returns. |
| RETURNS | The number of blocked tasks placed in <i>idList</i> . |
| SEE ALSO | semShow |

semInit()

semInit()

| | |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>semInit()</i> – initialize a static binary semaphore |
| SYNOPSIS | <pre>STATUS semInit (SEMAPHORE * pSemaphore /* 4.x semaphore to initialize */)</pre> |
| DESCRIPTION | This routine initializes static VxWorks 4.x semaphores. In some instances, a semaphore cannot be created with <i>semCreate()</i> but is a static object. |
| RETURNS | OK, or ERROR if the semaphore cannot be initialized. |
| SEE ALSO | <i>semOLib</i> , <i>semCreate()</i> |

semMCreate()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>semMCreate()</i> – create and initialize a mutual-exclusion semaphore |
| SYNOPSIS | <pre>SEM_ID semMCreate (int options /* mutex semaphore options */)</pre> |
| DESCRIPTION | <p>This routine allocates and initializes a mutual-exclusion semaphore. The semaphore state is initialized to full.</p> <p>Semaphore options include the following:</p> <p>SEM_Q_PRIORITY (0x1) Queue pending tasks on the basis of their priority.</p> <p>SEM_Q_FIFO (0x0) Queue pending tasks on a first-in-first-out basis.</p> <p>SEM_DELETE_SAFE (0x4) Protect a task that owns the semaphore from unexpected deletion. This option enables an implicit <i>taskSafe()</i> for each <i>semTake()</i>, and an implicit <i>taskUnsafe()</i> for each <i>semGive()</i>.</p> <p>SEM_INVERSION_SAFE (0x8) Protect the system from priority inversion. With this option, the task owning the</p> |

semaphore will execute at the highest priority of the tasks pended on the semaphore, if it is higher than its current priority. This option must be accompanied by the `SEM_Q_PRIORITY` queuing mode.

RETURNS The semaphore ID, or NULL if memory cannot be allocated.

SEE ALSO `semMLib`, `semLib`, `semBLib`, `taskSafe()`, `taskUnsafe()`

semMGiveForce()

NAME `semMGiveForce()` – give a mutual-exclusion semaphore without restrictions

SYNOPSIS

```
STATUS semMGiveForce
(
    SEM_ID semId /* semaphore ID to give */
)
```

DESCRIPTION This routine gives a mutual-exclusion semaphore, regardless of semaphore ownership. It is intended as a debugging aid only.

The routine is particularly useful when a task dies while holding some mutual-exclusion semaphore, because the semaphore can be resurrected. The routine will give the semaphore to the next task in the pend queue or make the semaphore full if no tasks are pending. In effect, execution will continue as if the task owning the semaphore had actually given the semaphore.

CAVEATS This routine should be used only as a debugging aid, when the condition of the semaphore is known.

RETURNS OK, or ERROR if the semaphore ID is invalid.

SEE ALSO `semMLib`, `semGive()`

semPxLibInit()

| | |
|--------------------|---------------------------------------------------------------------|
| NAME | <i>semPxLibInit()</i> – initialize POSIX semaphore support |
| SYNOPSIS | <code>STATUS semPxLibInit (void)</code> |
| DESCRIPTION | This routine must be called before using POSIX semaphores. |
| RETURNS | OK, or ERROR if there is an error installing the semaphore library. |
| SEE ALSO | <code>semPxLib</code> |

semPxShowInit()

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>semPxShowInit()</i> – initialize the POSIX semaphore show facility |
| SYNOPSIS | <code>STATUS semPxShowInit (void)</code> |
| DESCRIPTION | <p>This routine links the POSIX semaphore show routine into the VxWorks system. It is called automatically when the this show facility is configured into VxWorks using either of the following methods:</p> <ul style="list-style-type: none">– If you use the configuration header files, define <code>INCLUDE_SHOW_ROUTINES</code> in <code>config.h</code>.– If you use the Tornado project facility, select <code>INCLUDE_POSIX_SEM_SHOW</code>. |
| RETURNS | OK, or ERROR if an error occurs installing the file pointer show routine. |
| SEE ALSO | <code>semPxShow</code> |

semShow()

NAME *semShow()* – show information about a semaphore

SYNOPSIS

```
STATUS semShow
(
    SEM_ID semId, /* semaphore to display */
    int    level /* 0 = summary, 1 = details */
)
```

DESCRIPTION This routine displays the state and optionally the pended tasks of a semaphore. A summary of the state of the semaphore is displayed as follows:

```
Semaphore Id      : 0x585f2
Semaphore Type    : BINARY
Task Queuing      : PRIORITY
Pended Tasks      : 1
State              : EMPTY {Count if COUNTING, Owner if MUTEX}
```

If *level* is 1, then more detailed information will be displayed. If tasks are blocked on the queue, they are displayed in the order in which they will unblock, as follows:

| NAME | TID | PRI | DELAY |
|----------|--------|-----|-------|
| ----- | ----- | --- | ---- |
| tExcTask | 3fd678 | 0 | 21 |
| tLogTask | 3f8ac0 | 0 | 611 |

RETURNS OK or ERROR.

SEE ALSO *semShow*, *VxWorks Programmer's Guide: Target Shell*, *windsh*, *Tornado User's Guide: Shell*

semShowInit()

NAME *semShowInit()* – initialize the semaphore show facility

SYNOPSIS `void semShowInit (void)`

DESCRIPTION This routine links the semaphore show facility into the VxWorks system. It is called automatically when the semaphore show facility is configured into VxWorks using either of the following methods:

- If you use configuration header files, define `INCLUDE_SHOW_ROUTINES` in `config.h`.

semTake()

– If you use the Tornado project facility, select `INCLUDE_SEM_SHOW`.

RETURNS N/A

SEE ALSO `semShow`

semTake()

NAME `semTake()` – take a semaphore

SYNOPSIS

```
STATUS semTake
(
    SEM_ID semId, /* semaphore ID to take */
    int    timeout /* timeout in ticks */
)
```

DESCRIPTION This routine performs the take operation on a specified semaphore. Depending on the type of semaphore, the state of the semaphore and the calling task may be affected. The behavior of `semTake()` is discussed fully in the library description of the specific semaphore type being used.

A timeout in ticks may be specified. If a task times out, `semTake()` will return `ERROR`. Timeouts of `WAIT_FOREVER` (-1) and `NO_WAIT` (0) indicate to wait indefinitely or not to wait at all.

When `semTake()` returns due to timeout, it sets the `errno` to `S_objLib_OBJ_TIMEOUT` (defined in `objLib.h`).

The `semTake()` routine is not callable from interrupt service routines.

RETURNS `OK`, or `ERROR` if the semaphore ID is invalid or the task timed out.

ERRNO `S_intLib_NOT_ISR_CALLABLE`, `S_objLib_OBJ_ID_ERROR`, `S_objLib_OBJ_UNAVAILABLE`

SEE ALSO `semLib`, `semBLib`, `semCLib`, `semMLib`, `semSmLib`

sem_close()

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>sem_close()</i> – close a named semaphore (POSIX) |
| SYNOPSIS | <pre>int sem_close (sem_t * sem /* semaphore descriptor */)</pre> |
| DESCRIPTION | <p>This routine is called to indicate that the calling task is finished with the specified named semaphore, <i>sem</i>. Do not call this routine with an unnamed semaphore (i.e., one created by <i>sem_init()</i>); the effects are undefined. The <i>sem_close()</i> call deallocates any system resources allocated by the system for use by this task for this semaphore.</p> <p>If the semaphore has not been removed with a call to <i>sem_unlink()</i>, then <i>sem_close()</i> has no effect on the state of the semaphore. However, if the semaphore has been unlinked, the semaphore vanishes when the last task closes it.</p> |
| WARNING | Take care to avoid risking the deletion of a semaphore that another task has already locked. Applications should only close semaphores that the closing task has opened. |
| RETURNS | 0 (OK), or -1 (ERROR) if unsuccessful. |
| ERRNO | EINVAL – invalid semaphore descriptor. |
| SEE ALSO | <i>semPxBLib</i> , <i>sem_unlink()</i> , <i>sem_open()</i> , <i>sem_init()</i> |

sem_destroy()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>sem_destroy()</i> – destroy an unnamed semaphore (POSIX) |
| SYNOPSIS | <pre>int sem_destroy (sem_t * sem /* semaphore descriptor */)</pre> |
| DESCRIPTION | <p>This routine is used to destroy the unnamed semaphore indicated by <i>sem</i>.</p> <p>The <i>sem_destroy()</i> call can only destroy a semaphore created by <i>sem_init()</i>. Calling <i>sem_destroy()</i> with a named semaphore will cause a EINVAL error. Subsequent use of the <i>sem</i> semaphore will cause an EINVAL error in the calling function.</p> |

sem_getvalue()

If one or more tasks is blocked on the semaphore, the semaphore is not destroyed.

| | |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WARNING | Take care when deleting semaphores, particularly those used for mutual exclusion, to avoid deleting a semaphore out from under a task that has already locked that semaphore. Applications should adopt the protocol of only deleting semaphores that the deleting task has successfully locked. |
| RETURNS | 0 (OK), or -1 (ERROR) if unsuccessful. |
| ERRNO | EINVAL – invalid semaphore descriptor. EBUSY – one or more tasks is blocked on the semaphore. |
| SEE ALSO | semPxBLib , sem_init() |

sem_getvalue()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>sem_getvalue()</i> – get the value of a semaphore (POSIX) |
| SYNOPSIS | <pre>int sem_getvalue (sem_t * sem, /* semaphore descriptor */ int * sval /* buffer by which the value is returned */)</pre> |
| DESCRIPTION | <p>This routine updates the location referenced by the <i>sval</i> argument to have the value of the semaphore referenced by <i>sem</i> without affecting the state of the semaphore. The updated value represents an actual semaphore value that occurred at some unspecified time during the call, but may not be the actual value of the semaphore when it is returned to the calling task.</p> <p>If <i>sem</i> is locked, the value returned by <i>sem_getvalue()</i> will either be zero or a negative number whose absolute value represents the number of tasks waiting for the semaphore at some unspecified time during the call.</p> |
| RETURNS | 0 (OK), or -1 (ERROR) if unsuccessful. |
| ERRNO | EINVAL – invalid semaphore descriptor. |
| SEE ALSO | semPxBLib , sem_post() , sem_trywait() , sem_trywait() |

sem_init()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>sem_init()</i> – initialize an unnamed semaphore (POSIX) |
| SYNOPSIS | <pre>int sem_init (sem_t * sem, /* semaphore to be initialized */ int pshared, /* process sharing */ unsigned int value /* semaphore initialization value */)</pre> |
| DESCRIPTION | <p>This routine is used to initialize the unnamed semaphore <i>sem</i>. The value of the initialized semaphore is <i>value</i>. Following a successful call to <i>sem_init()</i> the semaphore may be used in subsequent calls to <i>sem_wait()</i>, <i>sem_trywait()</i>, and <i>sem_post()</i>. This semaphore remains usable until the semaphore is destroyed.</p> <p>The <i>pshared</i> parameter currently has no effect.</p> <p>Only <i>sem</i> itself may be used for synchronization.</p> |
| RETURNS | 0 (OK), or -1 (ERROR) if unsuccessful. |
| ERRNO | EINVAL – <i>value</i> exceeds SEM_VALUE_MAX . ENOSPC – unable to initialize semaphore due to resource constraints. |
| SEE ALSO | <i>semPxBLib</i> , <i>sem_wait()</i> , <i>sem_trywait()</i> , <i>sem_post()</i> |

sem_open()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>sem_open()</i> – initialize/open a named semaphore (POSIX) |
| SYNOPSIS | <pre>sem_t * sem_open (const char * name, /* semaphore name */ int oflag /* semaphore creation flags */)</pre> |
| DESCRIPTION | <p>This routine establishes a connection between a named semaphore and a task. Following a call to <i>sem_open()</i> with a semaphore name <i>name</i>, the task may reference the semaphore</p> |

sem_open()

associated with *name* using the address returned by this call. This semaphore may be used in subsequent calls to *sem_wait()*, *sem_trywait()*, and *sem_post()*. The semaphore remains usable until the semaphore is closed by a successful call to *sem_close()*.

The *oflag* argument controls whether the semaphore is created or merely accessed by the call to *sem_open()*. The following flag bits may be set in *oflag*:

O_CREAT

Use this flag to create a semaphore if it does not already exist. If **O_CREAT** is set and the semaphore already exists, **O_CREAT** has no effect except as noted below under **O_EXCL**. Otherwise, *sem_open()* creates a semaphore. **O_CREAT** requires a third and fourth argument: *mode*, which is of type *mode_t*, and *value*, which is of type unsigned int. *mode* has no effect in this implementation. The semaphore is created with an initial value of *value*. Valid initial values for semaphores must be less than or equal to **SEM_VALUE_MAX**.

O_EXCL

If **O_EXCL** and **O_CREAT** are set, *sem_open()* will fail if the semaphore name exists. If **O_EXCL** is set and **O_CREAT** is not set, the named semaphore is not created.

To determine whether a named semaphore already exists in the system, call *sem_open()* with the flags **O_CREAT** | **O_EXCL**. If the *sem_open()* call fails, the semaphore exists.

If a task makes multiple calls to *sem_open()* with the same value for *name*, then the same semaphore address is returned for each such call, provided that there have been no calls to *sem_unlink()* for this semaphore.

References to copies of the semaphore will produce undefined results.

NOTE

The current implementation has the following limitations:

- A semaphore cannot be closed with calls to *_exit()* or *exec()*.
- A semaphore cannot be implemented as a file.
- Semaphore names will not appear in the file system.

RETURNS

A pointer to *sem_t*, or -1 (ERROR) if unsuccessful.

ERRNO**EEXIST**

- **O_CREAT** | **O_EXCL** are set and the semaphore already exists.

EINVAL

- *value* exceeds **SEM_VALUE_MAX** or the semaphore name is invalid.

ENAMETOOLONG

- the semaphore name is too long.

ENOENT

- the named semaphore does not exist and **O_CREAT** is not set.

ENOSPC

- the semaphore could not be initialized due to resource constraints.

sem_post()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>sem_post()</i> – unlock (give) a semaphore (POSIX) |
| SYNOPSIS | <pre>int sem_post (sem_t * sem /* semaphore descriptor */)</pre> |
| DESCRIPTION | <p>This routine unlocks the semaphore referenced by <i>sem</i> by performing the semaphore unlock operation on that semaphore.</p> <p>If the semaphore value resulting from the operation is positive, then no tasks were blocked waiting for the semaphore to become unlocked; the semaphore value is simply incremented.</p> <p>If the value of the semaphore resulting from this semaphore is zero, then one of the tasks blocked waiting for the semaphore will return successfully from its call to <i>sem_wait()</i>.</p> |
| NOTE | <p>The _POSIX_PRIORITY_SCHEDULING functionality is not yet supported.</p> <p>Note that the POSIX terms <i>unlock</i> and <i>post</i> correspond to the term <i>give</i> used in other VxWorks semaphore documentation.</p> |
| RETURNS | 0 (OK), or -1 (ERROR) if unsuccessful. |
| ERRNO | EINVAL – invalid semaphore descriptor. |
| SEE ALSO | <i>semPxBLib</i> , <i>sem_wait()</i> , <i>sem_trywait()</i> |

sem_trywait()

| | |
|-----------------|----------------------------------------------------------------------------------------|
| NAME | <i>sem_trywait()</i> – lock (take) a semaphore, returning error if unavailable (POSIX) |
| SYNOPSIS | <pre>int sem_trywait (sem_t * sem /* semaphore descriptor */)</pre> |

sem_unlink()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | <p>This routine locks the semaphore referenced by <i>sem</i> only if the semaphore is currently not locked; that is, if the semaphore value is currently positive. Otherwise, it does not lock the semaphore. In either case, this call returns immediately without blocking.</p> <p>Upon return, the state of the semaphore is always locked (either as a result of this call or by a previous <i>sem_wait()</i> or <i>sem_trywait()</i>). The semaphore will remain locked until <i>sem_post()</i> is executed and returns successfully.</p> <p>Deadlock detection is not implemented.</p> <p>Note that the POSIX term <i>lock</i> corresponds to the term <i>take</i> used in other VxWorks semaphore documentation.</p> |
| RETURNS | 0 (OK), or -1 (ERROR) if unsuccessful. |
| ERRNO | <p>EAGAIN – semaphore is already locked.</p> <p>EINVAL – invalid semaphore descriptor.</p> |
| SEE ALSO | <i>semPxBLib</i> , <i>sem_wait()</i> , <i>sem_post()</i> |

sem_unlink()

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>sem_unlink()</i> – remove a named semaphore (POSIX) |
| SYNOPSIS | <pre>int sem_unlink (const char * name /* semaphore name */)</pre> |
| DESCRIPTION | <p>This routine removes the string <i>name</i> from the semaphore name table, and marks the corresponding semaphore for destruction. An unlinked semaphore is destroyed when the last task closes it with <i>sem_close()</i>. After a particular name is removed from the table, calls to <i>sem_open()</i> using the same name cannot connect to the same semaphore, even if other tasks are still using it. Instead, such calls refer to a new semaphore with the same name.</p> |
| RETURNS | 0 (OK), or -1 (ERROR) if unsuccessful. |
| ERRNO | <p>ENAMETOOLONG – semaphore name too long.</p> <p>ENOENT – named semaphore does not exist.</p> |
| SEE ALSO | <i>semPxBLib</i> , <i>sem_open()</i> , <i>sem_close()</i> |

sem_wait()

- NAME** *sem_wait()* – lock (take) a semaphore, blocking if not available (POSIX)
- SYNOPSIS**
- ```
int sem_wait
(
 sem_t * sem /* semaphore descriptor */
)
```
- DESCRIPTION**
- This routine locks the semaphore referenced by *sem* by performing the semaphore lock operation on that semaphore. If the semaphore value is currently zero, the calling task will not return from the call to *sem\_wait()* until it either locks the semaphore or the call is interrupted by a signal.
- On return, the state of the semaphore is locked and will remain locked until *sem\_post()* is executed and returns successfully.
- Deadlock detection is not implemented.
- Note that the POSIX term *lock* corresponds to the term *take* used in other VxWorks documentation regarding semaphores.
- RETURNS** 0 (OK), or -1 (ERROR) if unsuccessful.
- ERRNO** EINVAL  
– invalid semaphore descriptor, or semaphore destroyed while task waiting.
- SEE ALSO** *semPxBLib*, *sem\_trywait()*, *sem\_post()*

---

## *send()*

- NAME** *send()* – send data to a socket
- SYNOPSIS**
- ```
int send
(
    int s, /* socket to send to */
    char * buf, /* pointer to buffer to transmit */
    int buflen, /* length of buffer */
    int flags /* flags to underlying protocols */
)
```
- DESCRIPTION** This routine transmits data to a previously established connection-based (stream) socket.

sendmsg()

The maximum length of *buf* is subject to the limits on TCP buffer size; see the discussion of `SO_SNDBUF` in the `setsockopt()` manual entry.

You may OR the following values into the *flags* parameter with this operation:

`MSG_OOB` (0x1)

Out-of-band data.

`MSG_DONTROUTE` (0x4)

Send without using routing tables.

RETURNS The number of bytes sent, or `ERROR` if the call fails.

SEE ALSO `sockLib`, `setsockopt()`, `sendmsg()`

sendmsg()

NAME `sendmsg()` – send a message to a socket

SYNOPSIS

```
int sendmsg
(
    int          sd,      /* socket to send to */
    struct msghdr * mp,  /* scatter-gather message header */
    int          flags /* flags to underlying protocols */
)
```

DESCRIPTION This routine sends a message to a datagram socket. It may be used in place of `sendto()` to decrease the overhead of reconstructing the message-header structure (`msghdr`) for each message.

For BSD 4.4 sockets a copy of the `mp>msg_iov` array will be made. This requires a cluster from the network stack system pool of size `mp>msg_iovlen * sizeof(struct iovec)` or 8 bytes.

RETURNS The number of bytes sent, or `ERROR` if the call fails.

SEE ALSO `sockLib`, `sendto()`

sendto()

NAME *sendto()* – send a message to a socket

SYNOPSIS

```
int sendto
(
    int          s,          /* socket to send data to */
    caddr_t      buf,        /* pointer to data buffer */
    int          buflen,     /* length of buffer */
    int          flags,      /* flags to underlying protocols */
    struct sockaddr * to,    /* recipient's address */
    int          tolen       /* length of to sockaddr */
)
```

DESCRIPTION This routine sends a message to the datagram socket named by *to*. The socket *s* is received by the receiver as the sending socket.

The maximum length of *buf* is subject to the limits on UDP buffer size. See the discussion of `SO_SNDBUF` in the *setsockopt()* manual entry.

You can OR the following values into the *flags* parameter with this operation:

MSG_OOB (0x1)
Out-of-band data.

MSG_DONTROUTE (0x4)
Send without using routing tables.

RETURNS The number of bytes sent, or `ERROR` if the call fails.

SEE ALSO *sockLib*, *setsockopt()*

set_new_handler()

NAME *set_new_handler()* – set `new_handler` to user-defined function (C++)

SYNOPSIS `extern void (*set_new_handler (void(* pNewNewHandler)())) ()`

DESCRIPTION This function is used to define the function that will be called when operator `new` cannot allocate memory.

The `new_handler` acts for all threads in the system; you cannot set a different handler for different tasks.

set_terminate()

| | |
|----------------------|---------------------------------------------------------------|
| RETURNS | A pointer to the previous value of <code>new_handler</code> . |
| INCLUDE FILES | <code>new</code> |
| SEE ALSO | <code>cplusLib</code> |

set_terminate()

| | |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>set_terminate()</i> – set terminate to user-defined function (C++) |
| SYNOPSIS | <code>extern void (*set_terminate (void(* terminate_handler)())) ()</code> |
| DESCRIPTION | This function is used to define the <code>terminate_handler</code> which will be called when an uncaught exception is raised. The <code>terminate_handler</code> acts for all threads in the system; you cannot set a different handler for different tasks. |
| RETURNS | The previous <code>terminate_handler</code> . |
| INCLUDE FILES | <code>exception</code> |
| SEE ALSO | <code>cplusLib</code> |

setbuf()

| | |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>setbuf()</i> – specify the buffering for a stream (ANSI) |
| SYNOPSIS | <pre>void setbuf (FILE * fp, /* stream to set buffering for */ char * buf /* buffer to use */)</pre> |
| DESCRIPTION | Except that it returns no value, this routine is equivalent to <i>setvbuf()</i> invoked with the <i>mode</i> <code>_IOFBF</code> (full buffering) and <i>size</i> <code>BUFSIZ</code> , or (if <i>buf</i> is a null pointer), with the <i>mode</i> <code>_IONBF</code> (no buffering). |
| INCLUDE FILES | <code>stdio.h</code> |

RETURNS N/A

SEE ALSO `ansiStdio`, `setvbuf()`

setbuffer()

NAME `setbuffer()` – specify buffering for a stream

SYNOPSIS

```
void setbuffer
(
    FILE * fp, /* stream to set buffering for */
    char * buf, /* buffer to use */
    int size /* buffer size */
)
```

DESCRIPTION This routine specifies a buffer *buf* to be used for a stream in place of the automatically allocated buffer. If *buf* is NULL, the stream is unbuffered. This routine should be called only after the stream has been associated with an open file and before any other operation is performed on the stream.

This routine is provided for compatibility with earlier VxWorks releases.

INCLUDE FILES `stdio.h`

RETURNS N/A

SEE ALSO `ansiStdio`, `setvbuf()`

sethostname()

NAME `sethostname()` – set the symbolic name of this machine

SYNOPSIS

```
int sethostname
(
    char * name, /* machine name */
    int nameLen /* length of name */
)
```

DESCRIPTION This routine sets the target machine's symbolic name, which can be used for identification.

setjmp()

RETURNS OK or ERROR.

SEE ALSO **hostLib**

setjmp()

NAME *setjmp()* – save the calling environment in a **jmp_buf** argument (ANSI)

SYNOPSIS

```
int setjmp
(
    jmp_buf env
)
```

DESCRIPTION This routine saves the calling environment in *env*, in order to permit a *longjmp()* call to restore that environment (thus performing a non-local goto).

Constraints on Calling Environment

The *setjmp()* routine may only be used in the following contexts:

- as the entire controlling expression of a selection or iteration statement;
- as one operand of a relational or equality operator, in the controlling expression of a selection or iteration statement;
- as the operand of a single-argument ! operator, in the controlling expression of a selection or iteration statement; or
- as a complete C statement containing nothing other than the *setjmp()* call (though the result may be cast to **void**).

RETURNS * From a direct invocation, *setjmp()* returns zero. From a call to *longjmp()*, it returns a non-zero value specified as an argument to *longjmp()*.

SEE ALSO **ansiSetjmp**, *longjmp()*

setlinebuf()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>setlinebuf()</i> – set line buffering for standard output or standard error |
| SYNOPSIS | <pre>int setlinebuf (FILE * fp /* stream - stdout or stderr */)</pre> |
| DESCRIPTION | <p>This routine changes stdout or stderr streams from block-buffered or unbuffered to line-buffered. Unlike <i>setbuf()</i>, <i>setbuffer()</i>, or <i>setvbuf()</i>, it can be used at any time the stream is active.</p> <p>A stream can be changed from unbuffered or line-buffered to fully buffered using <i>freopen()</i>. A stream can be changed from fully buffered or line-buffered to unbuffered using <i>freopen()</i> followed by <i>setbuf()</i> with a buffer argument of NULL.</p> <p>This routine is provided for compatibility with earlier VxWorks releases.</p> |
| INCLUDE | stdio.h |
| RETURNS | OK, or ERROR if <i>fp</i> is not a valid stream. |
| SEE ALSO | ansiStdio |

setlocale()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>setlocale()</i> – set the appropriate locale (ANSI) |
| SYNOPSIS | <pre>char *setlocale (int category, /* category to change */ const char * localeName /* locale name */)</pre> |
| DESCRIPTION | <p>This function is included for ANSI compatibility. Only the default is implemented. At program start-up, the equivalent of the following is executed:</p> <pre>setlocale (LC_ALL, "C");</pre> <p>This specifies the program's entire locale and the minimal environment for C translation.</p> |

setsockopt()

| | |
|----------------------|------------------------------|
| INCLUDE FILES | locale.h, string.h, stdlib.h |
| RETURNS | A pointer to the string "C". |
| SEE ALSO | ansiLocale |

setsockopt()

NAME *setsockopt()* – set socket options

SYNOPSIS

```

STATUS setsockopt
(
    int    s,          /* target socket */
    int    level,     /* protocol level of option */
    int    optname,   /* option name */
    char * optval,    /* pointer to option value */
    int    optlen     /* option length */
)

```

DESCRIPTION This routine sets the options associated with a socket. To manipulate options at the "socket" level, *level* should be `SOL_SOCKET`. Any other levels should use the appropriate protocol number.

OPTIONS FOR STREAM SOCKETS

The following sections discuss the socket options available for stream (TCP) sockets.

SO_KEEPALIVE -- Detecting a Dead Connection

Specify the `SO_KEEPALIVE` option to make the transport protocol (TCP) initiate a timer to detect a dead connection:

```
setsockopt (sock, SOL_SOCKET, SO_KEEPALIVE, &optval, sizeof (optval));
```

This prevents an application from hanging on an invalid connection. The value at *optval* for this option is an integer (type `int`), either 1 (on) or 0 (off).

The integrity of a connection is verified by transmitting zero-length TCP segments triggered by a timer, to force a response from a peer node. If the peer does not respond after repeated transmissions of the `KEEPALIVE` segments, the connection is dropped, all protocol data structures are reclaimed, and processes sleeping on the connection are awakened with an `ETIMEDOUT` error.

The `ETIMEDOUT` timeout can happen in two ways. If the connection is not yet established, the `KEEPALIVE` timer expires after idling for `TCPTV_KEEP_INIT`. If the connection is established, the `KEEPALIVE` timer starts up when there is no traffic for

TCPTV_KEEP_IDLE. If no response is received from the peer after sending the KEEPALIVE segment TCPTV_KEEPCNT times with interval TCPTV_KEEPINTVL, TCP assumes that the connection is invalid. The parameters TCPTV_KEEP_INIT, TCPTV_KEEP_IDLE, TCPTV_KEEPCNT, and TCPTV_KEEPINTVL are defined in the file `target/h/net/tcp_timer.h`.

SO_LINGER -- Closing a Connection

Specify the `SO_LINGER` option to determine whether TCP should perform a "graceful" close:

```
setsockopt (sock, SOL_SOCKET, SO_LINGER, &optval, sizeof (optval));
```

For a "graceful" close in response to the shutdown of a connection, TCP tries to make sure that all the unacknowledged data in transmission channel are acknowledged, and the peer is shut down properly, by going through an elaborate set of state transitions.

The value at *optval* indicates the amount of time to linger if there is unacknowledged data, using `struct linger` in `target/h/sys/socket.h`. The `linger` structure has two members: `l_onoff` and `l_linger`. `l_onoff` can be set to 1 to turn on the `SO_LINGER` option, or set to 0 to turn off the `SO_LINGER` option. `l_linger` indicates the amount of time to linger. If `l_onoff` is turned on and `l_linger` is set to 0, a default value `TCP_LINGERTIME` (specified in `netinet/tcp_timer.h`) is used for incoming connections accepted on the socket.

When `SO_LINGER` is turned on and the `l_linger` field is set to 0, TCP simply drops the connection by sending out an RST if a connection is already established; frees up the space for the TCP protocol control block; and wakes up all tasks sleeping on the socket.

For the client side socket, the value of `l_linger` is not changed if it is set to 0. To make sure that the value of `l_linger` is 0 on a newly accepted socket connection, issue another `setsockopt()` after the `accept()` call.

Currently the exact value of `l_linger` time is actually ignored (other than checking for 0); that is, TCP performs the state transitions if `l_linger` is not 0, but does not explicitly use its value.

TCP_NODELAY -- Delivering Messages Immediately

Specify the `TCP_NODELAY` option for real-time protocols, such as the X Window System Protocol, that require immediate delivery of many small messages:

```
setsockopt (sock, IPPROTO_TCP, TCP_NODELAY, &optval, sizeof (optval));
```

The value at *optval* is an integer (type `int`) set to either 1 (on) or 0 (off).

By default, the VxWorks TCP implementation employs an algorithm that attempts to avoid the congestion that can be produced by a large number of small TCP segments. This typically arises with virtual terminal applications (such as telnet or rlogin) across networks that have low bandwidth and long delays. The algorithm attempts to have no more than one outstanding unacknowledged segment in the transmission channel while queueing up the rest of the smaller segments for later transmission. Another segment is

setsockopt()

sent only if enough new data is available to make up a maximum sized segment, or if the outstanding data is acknowledged.

This congestion-avoidance algorithm works well for virtual terminal protocols and bulk data transfer protocols such as FTP without any noticeable side effects. However, real-time protocols that require immediate delivery of many small messages, such as the X Window System Protocol, need to defeat this facility to guarantee proper responsiveness in their operation.

TCP_NODELAY is a mechanism to turn off the use of this algorithm. If this option is turned on and there is data to be sent out, TCP bypasses the congestion-avoidance algorithm: any available data segments are sent out if there is enough space in the send window.

SO_DEBUG -- Debugging the underlying protocol

Specify the SO_DEBUG option to let the underlying protocol module record debug information.

```
setsockopt (sock, SOL_SOCKET, SO_KEEPAALIVE, &optval, sizeof (optval));
```

The value at *optval* for this option is an integer (type **int**), either 1 (on) or 0 (off).

OPTION FOR DATAGRAM SOCKETS

The following section discusses an option for datagram (UDP) sockets.

SO_BROADCAST -- Sending to Multiple Destinations

Specify the SO_BROADCAST option when an application needs to send data to more than one destination:

```
setsockopt (sock, SOL_SOCKET, SO_BROADCAST, &optval, sizeof (optval));
```

The value at *optval* is an integer (type *int*), either 1 (on) or 0 (off).

OPTIONS FOR DATAGRAM AND RAW SOCKETS

The following section discusses options for multicasting on UDP and RAW sockets.

IP_ADD_MEMBERSHIP -- Join a Multicast Group

Specify the IP_ADD_MEMBERSHIP option when a process needs to join multicast group:

```
setsockopt (sock, IPPROTO_IP, IP_ADD_MEMBERSHIP, (char *)&ipMreq,
           sizeof (ipMreq));
```

The value of *ipMreq* is an **ip_mreq** structure. **ipMreq.imr_multiaddr.s_addr** is the internet multicast address **ipMreq.imr_interface.s_addr** is the internet unicast address of the interface through which the multicast packet needs to pass.

IP_DROP_MEMBERSHIP -- Leave a Multicast Group

Specify the IP_DROP_MEMBERSHIP option when a process needs to leave a previously joined multicast group:

```
setsockopt (sock, IPPROTO_IP, IP_DROP_MEMBERSHIP, (char *)&ipMreq,
           sizeof (ipMreq));
```

The value of *ipMreq* is an `ip_mreq` structure. `ipMreq.imr_multiaddr.s_addr` is the internet multicast address. `ipMreq.imr_interface.s_addr` is the internet unicast address of the interface to which the multicast address was bound.

IP_MULTICAST_IF -- Select a Default Interface for Outgoing Multicasts

Specify the `IP_MULTICAST_IF` option when an application needs to specify an outgoing network interface through which all multicast packets are sent:

```
setsockopt (sock, IPPROTO_IP, IP_MULTICAST_IF, (char *)&ifAddr,
           sizeof (mCastAddr));
```

The value of *ifAddr* is an `in_addr` structure. `ifAddr.s_addr` is the internet network interface address.

IP_MULTICAST_TTL -- Select a Default TTL

Specify the `IP_MULTICAST_TTL` option when an application needs to select a default TTL (time to live) for outgoing multicast packets:

```
setsockopt (sock, IPPROTO_IP, IP_MULTICAST_TTL, &optval, sizeof(optval));
```

The value at *optval* is an integer (type *int*), time to live value.

| optval(TTL) | Application | Scope |
|--------------------|-------------------------------|----------------|
| 0 | | same interface |
| 1 | | same subnet |
| 31 | local event video | |
| 32 | | same site |
| 63 | local event audio | |
| 64 | | same region |
| 95 | IETF channel 2 video | |
| 127 | IETF channel 1 video | |
| 128 | | same continent |
| 159 | IETF channel 2 audio | |
| 191 | IETF channel 1 audio | |
| 223 | IETF channel 2 low-rate audio | |
| 255 | IETF channel 1 low-rate audio | |
| | unrestricted in scope | |

IP_MULTICAST_LOOP -- Enable or Disable Loopback

Enable or disable loopback of outgoing multicasts.

```
setsockopt (sock, IPPROTO_IP, IP_MULTICAST_LOOP, &optval, sizeof(optval));
```

The value at *optval* is an integer (type *int*), either 1(on) or 0 (off).

setsockopt()**OPTIONS FOR BOTH STREAM AND DATAGRAM SOCKETS**

The following options can be used with either stream or datagram sockets.

SO_REUSEADDR -- Reusing a Socket Address

Specify **SO_REUSEADDR** to bind a stream socket to a local port that may be still bound to another stream socket:

```
setsockopt (sock, SOL_SOCKET, SO_REUSEADDR, &optval, sizeof (optval));
```

The value at *optval* is an integer (type *int*), either 1 (on) or 0 (off).

When the **SO_REUSEADDR** option is turned on, applications may bind a stream socket to a local port even if it is still bound to another stream socket, if that other socket is associated with a "zombie" protocol control block context not yet freed from previous sessions. The uniqueness of port number combinations for each connection is still preserved through sanity checks performed at actual connection setup time. If this option is not turned on and an application attempts to bind to a port which is being used by a zombie protocol control block, the *bind()* call fails.

SO_SNDBUF -- Specifying the Size of the Send Buffer

Specify **SO_SNDBUF** to adjust the maximum size of the socket-level send buffer:

```
setsockopt (sock, SOL_SOCKET, SO_SNDBUF, &optval, sizeof (optval));
```

The value at *optval* is an integer (type **int**) that specifies the size of the socket-level send buffer to be allocated.

When stream or datagram sockets are created, each transport protocol reserves a set amount of space at the socket level for use when the sockets are attached to a protocol. For TCP, the default size of the send buffer is 8192 bytes. For UDP, the default size is 9216 bytes. Socket-level buffers are allocated dynamically from the mbuf pool.

The effect of setting the maximum size of buffers (for both **SO_SNDBUF** and **SO_RCVBUF**, described below) is not actually to allocate the mbufs from the mbuf pool, but to set the high-water mark in the protocol data structure which is used later to limit the amount of mbuf allocation. Thus, the maximum size specified for the socket level send and receive buffers can affect the performance of bulk data transfers. For example, the size of the TCP receive windows is limited by the remaining socket-level buffer space. These parameters must be adjusted to produce the optimal result for a given application.

SO_RCVBUF -- Specifying the Size of the Receive Buffer

Specify **SO_RCVBUF** to adjust the maximum size of the socket-level receive buffer:

```
setsockopt (sock, SOL_SOCKET, SO_RCVBUF, &optval, sizeof (optval));
```

The value at *optval* is an integer (type **int**) that specifies the size of the socket-level receive buffer to be allocated.

When stream or datagram sockets are created, each transport protocol reserves a set amount of space at the socket level for use when the sockets are attached to a protocol.

For TCP, the default size is 8192 bytes. UDP reserves 41600 bytes, enough space for up to forty incoming datagrams (1 Kbyte each).

See the `SO_SNDBUF` discussion above for a discussion of the impact of buffer size on application performance.

SO_OOBINLINE – Placing Urgent Data in the Normal Data Stream

Specify the `SO_OOBINLINE` option to place urgent data within the normal receive data stream:

```
setsockopt (sock, SOL_SOCKET, SO_OOBINLINE, &optval, sizeof (optval));
```

TCP provides an expedited data service which does not conform to the normal constraints of sequencing and flow control of data streams. The expedited service delivers "out-of-band" (urgent) data ahead of other "normal" data to provide interrupt-like services (for example, when you hit a CTRL-C during telnet or rlogin session while data is being displayed on the screen.)

TCP does not actually maintain a separate stream to support the urgent data. Instead, urgent data delivery is implemented as a pointer (in the TCP header) which points to the sequence number of the octet following the urgent data. If more than one transmission of urgent data is received from the peer, they are all put into the normal stream. This is intended for applications that cannot afford to miss out on any urgent data but are usually too slow to respond to them promptly.

RETURNS OK, or ERROR if there is an invalid socket, an unknown option, an option length greater than MLEN, insufficient mbufs, or the call is unable to set the specified option.

SEE ALSO `sockLib`

setvbuf()

NAME `setvbuf()` – specify buffering for a stream (ANSI)

SYNOPSIS

```
int setvbuf
(
    FILE * fp,      /* stream to set buffering for */
    char * buf,    /* buffer to use (optional) */
    int  mode,     /* _IOFBF = fully buffered */
                /* _IOLBF = line buffered */
                /* _IONBF = unbuffered */
    size_t size    /* buffer size */
)
```

shell()

DESCRIPTION This routine sets the buffer size and buffering mode for a specified stream. It should be called only after the stream has been associated with an open file and before any other operation is performed on the stream. The argument *mode* determines how the stream will be buffered, as follows:

`_IOFBF`
input/output is to be fully buffered.

`_IOLBF`
input/output is to be line buffered.

`_IONBF`
input/output is to be unbuffered.

If *buf* is not a null pointer, the array it points to may be used instead of a buffer allocated by *setvbuf()*. The argument *size* specifies the size of the array. The contents of the array at any time are indeterminate.

INCLUDE FILES `stdio.h`

RETURNS Zero, or non-zero if *mode* is invalid or the request cannot be honored.

SEE ALSO `ansiStdio`

shell()

NAME *shell()* – the shell entry point

SYNOPSIS

```
void shell
(
    BOOL interactive /* should be TRUE, except for a script */
)
```

DESCRIPTION This routine is the shell task. It is called with a single parameter indicating whether this is an interactive shell to be used from a terminal or a socket, or a shell that executes a script.

Normally, the shell is spawned in interactive mode by the root task, *usrRoot()*, when VxWorks starts up. After that, *shell()* is called only to execute scripts, or when the shell is restarted after an abort.

The shell gets its input from standard input and sends output to standard output. Both standard input and standard output are initially assigned to the console, but are redirected by *telnetdTask()* and *rlogindTask()*.

The shell is not reentrant, since *yacc* does not generate a reentrant parser. Therefore, there can be only a single shell executing at one time.

RETURNS N/A

SEE ALSO **shellLib**, *VxWorks Programmer's Guide: Target Shell*

shellHistory()

NAME *shellHistory()* – display or set the size of shell history

SYNOPSIS

```
void shellHistory
(
    int size /* 0 = display, >0 = set history to new size */
)
```

DESCRIPTION This routine displays shell history, or resets the default number of commands displayed by shell history to *size*. By default, history size is 20 commands. Shell history is actually maintained by **ledLib**.

RETURNS N/A

SEE ALSO **shellLib**, **ledLib**, **h()**, *VxWorks Programmer's Guide: Target Shell*, **windsh**, *Tornado User's Guide: Shell*

shellInit()

NAME *shellInit()* – start the shell

SYNOPSIS

```
STATUS shellInit
(
    int stackSize, /* shell stack (0 = previous/default value) */
    int arg        /* argument to shell task */
)
```

DESCRIPTION This routine starts the shell task. If the configuration macro **INCLUDE_SHELL** is defined, *shellInit()* is called by the root task, *usrRoot()*, in **usrConfig.c**.

RETURNS OK or ERROR.

SEE ALSO **shellLib**, *VxWorks Programmer's Guide: Target Shell*

shellLock()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>shellLock()</i> – lock access to the shell |
| SYNOPSIS | <pre>BOOL shellLock (BOOL request /* TRUE = lock, FALSE = unlock */)</pre> |
| DESCRIPTION | This routine locks or unlocks access to the shell. When locked, cooperating tasks, such as <i>telnetdTask()</i> and <i>rlogindTask()</i> , will not take the shell. |
| RETURNS | TRUE if <i>request</i> is "lock" and the routine successfully locks the shell, otherwise FALSE. TRUE if <i>request</i> is "unlock" and the routine successfully unlocks the shell, otherwise FALSE. |
| SEE ALSO | <i>shellLib</i> , <i>VxWorks Programmer's Guide: Target Shell</i> |

shellOrigStdSet()

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>shellOrigStdSet()</i> – set the shell's default input/output/error file descriptors |
| SYNOPSIS | <pre>void shellOrigStdSet (int which, /* STD_IN, STD_OUT, STD_ERR */ int fd /* fd to be default */)</pre> |
| DESCRIPTION | This routine is called to change the shell's default standard input/output/error file descriptor. Normally, it is used only by the shell, <i>rlogindTask()</i> , and <i>telnetdTask()</i> . Values for <i>which</i> can be <i>STD_IN</i> , <i>STD_OUT</i> , or <i>STD_ERR</i> , as defined in <i>vxWorks.h</i> . Values for <i>fd</i> can be the file descriptor for any file or device. |
| RETURNS | N/A |
| SEE ALSO | <i>shellLib</i> |

shellPromptSet()

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>shellPromptSet()</i> – change the shell prompt |
| SYNOPSIS | <pre>void shellPromptSet (char * newPrompt /* string to become new shell prompt */)</pre> |
| DESCRIPTION | This routine changes the shell prompt string to <i>newPrompt</i> . |
| RETURNS | N/A |
| SEE ALSO | shellLib , <i>VxWorks Programmer's Guide: Target Shell</i> , windsh , <i>Tornado User's Guide: Shell</i> |

shellScriptAbort()

| | |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>shellScriptAbort()</i> – signal the shell to stop processing a script |
| SYNOPSIS | <pre>void shellScriptAbort (void)</pre> |
| DESCRIPTION | This routine signals the shell to abort processing a script file. It can be called from within a script if an error is detected. |
| RETURNS | N/A |
| SEE ALSO | shellLib , <i>VxWorks Programmer's Guide: Target Shell</i> |

show()

| | |
|-----------------|-----------------------------------------------------------------------------------------------|
| NAME | <i>show()</i> – print information on a specified object |
| SYNOPSIS | <pre>void show (int objId, /* object ID */ int level /* information level */)</pre> |

shutdown()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | This command prints information on the specified object. System objects include tasks, local and shared semaphores, local and shared message queues, local and shared memory partitions, watchdogs, and symbol tables. An information level is interpreted by the objects show routine on a class by class basis. Refer to the object's library manual page for more information. |
| RETURNS | N/A |
| SEE ALSO | usrLib , i() , ti() , lkup() , <i>VxWorks Programmer's Guide: Target Shell</i> , windsh , <i>Tornado User's Guide: Shell</i> |

shutdown()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | shutdown() – shut down a network connection |
| SYNOPSIS | <pre>STATUS shutdown (int s, /* socket to shut down */ int how /* 0 = receives disallowed */ /* 1 = sends disallowed */ /* 2 = sends and receives disallowed */) </pre> |
| DESCRIPTION | This routine shuts down all, or part, of a connection-based socket <i>s</i> . If the value of <i>how</i> is 0, receives are disallowed. If <i>how</i> is 1, sends are disallowed. If <i>how</i> is 2, both sends and receives are disallowed. |
| RETURNS | OK, or ERROR if the socket is invalid or not connected. |
| SEE ALSO | sockLib |

sigaction()

| | |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | sigaction() – examine and/or specify the action associated with a signal (POSIX) |
| SYNOPSIS | <pre>int sigaction (int signo, /* signal of handler of interest */ const struct sigaction * pAct, /* location of new handler */ </pre> |

```

        struct sigaction *      pOact /* location to store old handler */
    )

```

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | This routine allows the calling process to examine and/or specify the action to be associated with a specific signal. |
| RETURNS | OK (0), or ERROR (-1) if the signal number is invalid. |
| ERRNO | EINVAL |
| SEE ALSO | sigLib |

sigaddset()

NAME *sigaddset()* – add a signal to a signal set (POSIX)

SYNOPSIS

```

int sigaddset
(
    sigset_t * pSet, /* signal set to add signal to */
    int      signo /* signal to add */
)

```

DESCRIPTION This routine adds the signal specified by *signo* to the signal set specified by *pSet*.

RETURNS OK (0), or ERROR (-1) if the signal number is invalid.

ERRNO EINVAL

SEE ALSO sigLib

sigblock()

NAME *sigblock()* – add to a set of blocked signals

SYNOPSIS

```

int sigblock
(
    int mask /* mask of additional signals to be blocked */
)

```

sigdelset()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | This routine adds the signals in <i>mask</i> to the task's set of blocked signals. A one (1) in the bit mask indicates that the specified signal is blocked from delivery. Use the macro SIGMASK to construct the mask for a specified signal number. |
| RETURNS | The previous value of the signal mask. |
| SEE ALSO | sigLib , sigprocmask() |

sigdelset()

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>sigdelset()</i> – delete a signal from a signal set (POSIX) |
| SYNOPSIS | <pre>int sigdelset (sigset_t * pSet, /* signal set to delete signal from */ int signo /* signal to delete */)</pre> |
| DESCRIPTION | This routine deletes the signal specified by <i>signo</i> from the signal set specified by <i>pSet</i> . |
| RETURNS | OK (0), or ERROR (-1) if the signal number is invalid. |
| ERRNO | EINVAL |
| SEE ALSO | sigLib |

sigemptyset()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------|
| NAME | <i>sigemptyset()</i> – initialize a signal set with no signals included (POSIX) |
| SYNOPSIS | <pre>int sigemptyset (sigset_t * pSet /* signal set to initialize */)</pre> |
| DESCRIPTION | This routine initializes the signal set specified by <i>pSet</i> , such that all signals are excluded. |
| RETURNS | OK (0), or ERROR (-1) if the signal set cannot be initialized. |

ERRNO No errors are detectable.

SEE ALSO sigLib

sigfillset()

NAME *sigfillset()* – initialize a signal set with all signals included (POSIX)

SYNOPSIS

```
int sigfillset
(
    sigset_t * pSet /* signal set to initialize */
)
```

DESCRIPTION This routine initializes the signal set specified by *pSet*, such that all signals are included.

RETURNS OK (0), or ERROR (-1) if the signal set cannot be initialized.

ERRNO No errors are detectable.

SEE ALSO sigLib

sigInit()

NAME *sigInit()* – initialize the signal facilities

SYNOPSIS

```
int sigInit (void)
```

DESCRIPTION This routine initializes the signal facilities. It is usually called from the system start-up routine *usrInit()* in *usrConfig*, before interrupts are enabled.

RETURNS OK, or ERROR if the delete hooks cannot be installed.

ERRNO S_taskLib_TASK_HOOK_TABLE_FULL

SEE ALSO sigLib

sigismember()

sigismember()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>sigismember()</i> – test to see if a signal is in a signal set (POSIX) |
| SYNOPSIS | <pre>int sigismember (const sigset_t * pSet, /* signal set to test */ int signo /* signal to test for */)</pre> |
| DESCRIPTION | This routine tests whether the signal specified by <i>signo</i> is a member of the set specified by <i>pSet</i> . |
| RETURNS | 1 if the specified signal is a member of the specified set, OK (0) if it is not, or ERROR (-1) if the test fails. |
| ERRNO | EINVAL |
| SEE ALSO | sigLib |

signal()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>signal()</i> – specify the handler associated with a signal |
| SYNOPSIS | <pre>void (*signal (int signo, void (*pHandler) ())) ()</pre> |
| DESCRIPTION | This routine chooses one of three ways in which receipt of the signal number <i>signo</i> is to be subsequently handled. If the value of <i>pHandler</i> is SIG_DFL , default handling for that signal will occur. If the value of <i>pHandler</i> is SIG_IGN , the signal will be ignored. Otherwise, <i>pHandler</i> must point to a function to be called when that signal occurs. |
| RETURNS | The value of the previous signal handler, or SIG_ERR . |
| SEE ALSO | sigLib |

sigpending()

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>sigpending()</i> – retrieve the set of pending signals blocked from delivery (POSIX) |
| SYNOPSIS | <pre>int sigpending (sigset_t * pSet /* location to store pending signal set */)</pre> |
| DESCRIPTION | This routine stores the set of signals that are blocked from delivery and that are pending for the calling process in the space pointed to by <i>pSet</i> . |
| RETURNS | OK (0), or ERROR (-1) if the signal TCB cannot be allocated. |
| ERRNO | ENOMEM |
| SEE ALSO | sigLib |

sigprocmask()

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>sigprocmask()</i> – examine and/or change the signal mask (POSIX) |
| SYNOPSIS | <pre>int sigprocmask (int how, /* how signal mask will be changed */ const sigset_t * pSet, /* location of new signal mask */ sigset_t * pOset /* location to store old signal mask */)</pre> |
| DESCRIPTION | <p>This routine allows the calling process to examine and/or change its signal mask. If the value of <i>pSet</i> is not NULL, it points to a set of signals to be used to change the currently blocked set.</p> <p>The value of <i>how</i> indicates the manner in which the set is changed and consists of one of the following, defined in signal.h:</p> <p>SIG_BLOCK the resulting set is the union of the current set and the signal set pointed to by <i>pSet</i>.</p> <p>SIG_UNBLOCK the resulting set is the intersection of the current set and the complement of the signal set pointed to by <i>pSet</i>.</p> |

SIG_SETMASK

the resulting set is the signal set pointed to by *pSset*.

RETURNS OK (0), or ERROR (-1) if *how* is invalid.

ERRNO EINVAL

SEE ALSO *sigLib*, *sigsetmask()*, *sigblock()*

sigqueue()

NAME *sigqueue()* – send a queued signal to a task

SYNOPSIS

```
int sigqueue
(
    int          tid,
    int          signo,
    const union sigval value
)
```

DESCRIPTION The function *sigqueue()* sends the signal specified by *signo* with the signal-parameter value specified by *value* to the process specified by *tid*.

RETURNS OK (0), or ERROR (-1) if the task ID or signal number is invalid, or if there are no queued-signal buffers available.

ERRNO EINVAL EAGAIN

SEE ALSO *sigLib*

sigqueueInit()

NAME *sigqueueInit()* – initialize the queued signal facilities

SYNOPSIS

```
int sigqueueInit
(
    int nQueues
)
```

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | <p>This routine initializes the queued signal facilities. It must be called before any call to <i>sigqueue()</i>. It is usually called from the system start-up routine <i>usrInit()</i> in <i>usrConfig</i>, after <i>sysInit()</i> is called.</p> <p>It allocates <i>nQueues</i> buffers to be used by <i>sigqueue()</i>. A buffer is used by each call to <i>sigqueue()</i> and freed when the signal is delivered (thus if a signal is block, the buffer is unavailable until the signal is unblocked.)</p> |
| RETURNS | OK, or ERROR if memory could not be allocated. |
| SEE ALSO | <i>sigLib</i> |

sigsetmask()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>sigsetmask()</i> – set the signal mask |
| SYNOPSIS | <pre>int sigsetmask (int mask /* new signal mask */)</pre> |
| DESCRIPTION | <p>This routine sets the calling task's signal mask to a specified value. A one (1) in the bit mask indicates that the specified signal is blocked from delivery. Use the macro SIGMASK to construct the mask for a specified signal number.</p> |
| RETURNS | The previous value of the signal mask. |
| SEE ALSO | <i>sigLib</i> , <i>sigprocmask()</i> |

sigsuspend()

| | |
|-----------------|-------------------------------------------------------------------------------------------|
| NAME | <i>sigsuspend()</i> – suspend the task until delivery of a signal (POSIX) |
| SYNOPSIS | <pre>int sigsuspend (const sigset_t * pset /* signal mask while suspended */)</pre> |

sigtimedwait()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | This routine suspends the task until delivery of a signal. While suspended, <i>pSet</i> is used as the set of masked signals. |
| NOTE | Since the <i>sigsuspend()</i> function suspends thread execution indefinitely, there is no successful completion return value. |
| RETURNS | -1, always. |
| ERRNO | EINTR |
| SEE ALSO | sigLib |

sigtimedwait()

NAME *sigtimedwait()* – wait for a signal

SYNOPSIS

```
int sigtimedwait
(
    const sigset_t *    pSet,      /* the signal mask while suspended */
    struct siginfo *   pInfo,     /* return value */
    const struct timespec * pTimeout
)
```

DESCRIPTION The function *sigtimedwait()* selects the pending signal from the set specified by *pSet*. If multiple signals in *pSet* are pending, it will remove and return the lowest numbered one. If no signal in *pSet* is pending at the time of the call, the task will be suspended until one of the signals in *pSet* becomes pending, it is interrupted by an unblocked caught signal, or until the time interval specified by *pTimeout* has expired. If *pTimeout* is NULL, then the timeout interval is forever.

If the *pInfo* argument is non-NULL, the selected signal number is stored in the **si_signo** member, and the cause of the signal is stored in the **si_code** member. If the signal is a queued signal, the value is stored in the **si_value** member of *pInfo*; otherwise the content of **si_value** is undefined.

The following values are defined in **signal.h** for **si_code**:

SI_USER
the signal was sent by the *kill()* function.

SI_QUEUE
the signal was sent by the *sigqueue()* function.

SI_TIMER
the signal was generated by the expiration of a timer set by *timer_settime()*.

SI_ASYNCIO

the signal was generated by the completion of an asynchronous I/O request.

SI_MSGQ

the signal was generated by the arrival of a message on an empty message queue.

The function *sigtimedwait()* provides a synchronous mechanism for tasks to wait for asynchronously generated signals. A task should use *sigprocmask()* to block any signals it wants to handle synchronously and leave their signal handlers in the default state. The task can then make repeated calls to *sigtimedwait()* to remove any signals that are sent to it.

RETURNS

Upon successful completion (that is, one of the signals specified by *pSet* is pending or is generated) *sigtimedwait()* will return the selected signal number. Otherwise, a value of -1 is returned and **errno** is set to indicate the error.

ERRNO**EINTR**

The wait was interrupted by an unblocked, caught signal.

EAGAIN

No signal specified by *pSet* was delivered within the specified timeout period.

EINVAL

The *pTimeout* argument specified a **tv_nsec** value less than zero or greater than or equal to 1000 million.

SEE ALSO

sigLib

sigvec()

NAME

sigvec() – install a signal handler

SYNOPSIS

```
int sigvec
(
    int                sig, /* signal to attach handler to */
    const struct sigvec * pVec, /* new handler information */
    struct sigvec *     pOvec /* previous handler information */
)
```

DESCRIPTION

This routine binds a signal handler routine referenced by *pVec* to a specified signal *sig*. It can also be used to determine which handler, if any, has been bound to a particular signal: *sigvec()* copies current signal handler information for *sig* to *pOvec* and does not install a signal handler if *pVec* is set to NULL (0).

sigwaitinfo()

Both *pVec* and *pOvec* are pointers to a structure of type **struct sigvec**. The information passed includes not only the signal handler routine, but also the signal mask and additional option bits. The structure **sigvec** and the available options are defined in **signal.h**.

| | |
|-----------------|----------------------------------------------------------------------------------------------|
| RETURNS | OK (0), or ERROR (-1) if the signal number is invalid or the signal TCB cannot be allocated. |
| ERRNO | EINVAL, ENOMEM |
| SEE ALSO | sigLib |

sigwaitinfo()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>sigwaitinfo()</i> – wait for real-time signals |
| SYNOPSIS | <pre>int sigwaitinfo (const sigset_t * pSet, /* the signal mask while suspended */ struct siginfo * pInfo /* return value */)</pre> |
| DESCRIPTION | The function <i>sigwaitinfo()</i> is equivalent to calling <i>sigtimedwait()</i> with <i>pTimeout</i> equal to NULL. See that manual entry for more information. |
| RETURNS | Upon successful completion (that is, one of the signals specified by <i>pSet</i> is pending or is generated) <i>sigwaitinfo()</i> returns the selected signal number. Otherwise, a value of -1 is returned and errno is set to indicate the error. |
| ERRNO | EINTR The wait was interrupted by an unblocked, caught signal. |
| SEE ALSO | sigLib |

sin()

| | |
|----------------------|---------------------------------------------------------------------------------------------------|
| NAME | <i>sin()</i> – compute a sine (ANSI) |
| SYNOPSIS | <pre>double sin (double x /* angle in radians */)</pre> |
| DESCRIPTION | This routine computes the sine of x in double precision. The angle x is expressed in radians. |
| INCLUDE FILES | math.h |
| RETURNS | The double-precision sine of x . |
| SEE ALSO | ansiMath, mathALib |

sincos()

| | |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>sincos()</i> – compute both a sine and cosine |
| SYNOPSIS | <pre>void sincos (double x, /* angle in radians */ double * sinResult, /* sine result buffer */ double * cosResult /* cosine result buffer */)</pre> |
| DESCRIPTION | This routine computes both the sine and cosine of x in double precision. The sine is copied to <i>sinResult</i> and the cosine is copied to <i>cosResult</i> . |
| INCLUDE FILES | math.h |
| RETURNS | N/A |
| SEE ALSO | mathALib |

sincosf()

sincosf()

NAME *sincosf()* – compute both a sine and cosine

SYNOPSIS

```
void sincosf
(
    float x,          /* angle in radians */
    float * sinResult, /* sine result buffer */
    float * cosResult /* cosine result buffer */
)
```

DESCRIPTION This routine computes both the sine and cosine of x in single precision. The sine is copied to *sinResult* and the cosine is copied to *cosResult*. The angle x is expressed in radians.

INCLUDE FILES **math.h**

RETURNS N/A

SEE ALSO **mathALib**

sinf()

NAME *sinf()* – compute a sine (ANSI)

SYNOPSIS

```
float sinf
(
    float x /* angle in radians */
)
```

DESCRIPTION This routine returns the sine of x in single precision. The angle x is expressed in radians.

INCLUDE FILES **math.h**

RETURNS The single-precision sine of x .

SEE ALSO **mathALib**

sinh()

| | |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>sinh()</i> – compute a hyperbolic sine (ANSI) |
| SYNOPSIS | <pre>double sinh (double x /* number whose hyperbolic sine is required */)</pre> |
| DESCRIPTION | This routine returns the hyperbolic sine of x in double precision (IEEE double, 53 bits). A range error occurs if x is too large. |
| INCLUDE FILES | math.h |
| RETURNS | The double-precision hyperbolic sine of x . Special cases: If x is +INF, -INF, or NaN, <i>sinh()</i> returns x . |
| SEE ALSO | ansiMath, mathALib |

sinhf()

| | |
|----------------------|---------------------------------------------------------------------------------------|
| NAME | <i>sinhf()</i> – compute a hyperbolic sine (ANSI) |
| SYNOPSIS | <pre>float sinhF (float x /* number whose hyperbolic sine is required */)</pre> |
| DESCRIPTION | This routine returns the hyperbolic sine of x in single precision. |
| INCLUDE FILES | math.h |
| RETURNS | The single-precision hyperbolic sine of x . |
| SEE ALSO | mathALib |

slattach()

NAME *slattach()* – publish the `sl` network interface and initialize the driver and device

SYNOPSIS

```
STATUS slattach
(
    int unit,          /* SLIP device unit number */
    int fd,           /* fd of tty device for SLIP interface */
    BOOL compressEnable, /* explicitly enable CSLIP compression */
    BOOL compressAllow, /* enable CSLIP compression on Rx */
    int mtu           /* user settable MTU */
)
```

DESCRIPTION This routine publishes the `sl` interface by filling in a network interface record and adding this record to the system list. It also initializes the driver and the device to the operational state.

This routine is usually called by *slipInit()*.

RETURNS OK or ERROR.

SEE ALSO `if_sl`

slipBaudSet()

NAME *slipBaudSet()* – set the baud rate for a SLIP interface

SYNOPSIS

```
STATUS slipBaudSet
(
    int unit, /* SLIP device unit number */
    int baud /* baud rate */
)
```

DESCRIPTION This routine adjusts the baud rate of a tty device attached to a SLIP interface. It provides a way to modify the baud rate of a tty device being used as a SLIP interface.

RETURNS OK, or ERROR if the unit number is invalid or uninitialized.

SEE ALSO `if_sl`

slipDelete()

NAME *slipDelete()* – delete a SLIP interface

SYNOPSIS

```
STATUS slipDelete
(
    int unit /* SLIP unit number */
)
```

DESCRIPTION This routine resets a specified SLIP interface. It detaches the tty from the `sl` unit and deletes the specified SLIP interface from the list of network interfaces. For example, the following call will delete the first SLIP interface from the list of network interfaces:

```
slipDelete (0);
```

RETURNS OK, or ERROR if the unit number is invalid or uninitialized.

SEE ALSO `if_sl`

slipInit()

NAME *slipInit()* – initialize a SLIP interface

SYNOPSIS

```
STATUS slipInit
(
    int    unit,           /* SLIP device unit number (0 - 19) */
    char * devName,       /* name of the tty device to be initialized */
    char * myAddr,        /* address of the SLIP interface */
    char * peerAddr,     /* address of the remote peer SLIP interface */
    int    baud,          /* baud rate of SLIP device: 0=don't set rate */
    BOOL   compressEnable, /* explicitly enable CSLIP compression */
    BOOL   compressAllow, /* enable CSLIP compression on Rx */
    int    mtu            /* user set-able MTU */
)
```

DESCRIPTION This routine initializes a SLIP device. Its parameters specify the name of the tty device, the Internet addresses of both sides of the SLIP point-to-point link (i.e., the local and remote sides of the serial line connection), and CSLIP options.

The Internet address of the local side of the connection is specified in *myAddr* and the name of its tty device is specified in *devName*. The Internet address of the remote side is

smIfAttach()

specified in *peerAddr*. If *baud* is not zero, the baud rate will be the specified value; otherwise, the default baud rate will be the rate set by the tty driver. The *unit* parameter specifies the SLIP device unit number. Up to twenty units may be created.

The CLSIP options parameters *compressEnable* and *compressAllow* determine support for TCP/IP header compression. If *compressAllow* is TRUE (1), then CSLIP will be enabled only if a CSLIP type packet is received by this device. If *compressEnable* is TRUE (1), then CSLIP compression will be enabled explicitly for all transmitted packets, and compressed packets can be received.

The MTU option parameter allows the setting of the MTU for the link.

For example, the following call initializes a SLIP device, using the console's second port, where the Internet address of the local host is 192.10.1.1 and the address of the remote host is 192.10.1.2. The baud rate will be the default rate for /tyCo/1. CLSIP is enabled if a CSLIP type packet is received. The MTU of the link is 1006.

```
slipInit (0, "/tyCo/1", "192.10.1.1", "192.10.1.2", 0, 0, 1, 1006);
```

RETURNS OK, or ERROR if the device cannot be opened, memory is insufficient, or the route is invalid.

SEE ALSO [if_sl](#)

smIfAttach()

NAME *smIfAttach()* – publish the **sm** interface and initialize the driver and device

SYNOPSIS STATUS *smIfAttach*

```
(
  int          unit,          /* interface unit number */
  SM_ANCHOR * pAnchor,      /* local addr of anchor */
  int          maxInputPkts, /* max no. of input pkts */
  int          intType,      /* method of notif. */
  int          intArg1,      /* interrupt argument #1 */
  int          intArg2,      /* interrupt argument #2 */
  int          intArg3,      /* interrupt argument #3 */
  int          ticksPerBeat, /* heartbeat freq. */
  int          numLoan       /* no. of buffers to loan */
)
```

DESCRIPTION This routine attaches an **sm** Ethernet interface to the network, if the interface exists. This routine makes the interface available by filling in the network interface record. The system will initialize the interface when it is ready to accept packets.

The shared memory region must have been initialized, via *smPktSetup()*, prior to calling this routine (typically by an OS-specific initialization routine). The *smIfAttach()* routine can be called only once per unit number.

The *pAnchor* parameter is the local address by which the local CPU may access the shared memory anchor.

The *maxInputPkts* parameter specifies the maximum number of incoming shared memory packets which may be queued to this CPU at one time.

The *intType*, *intArg1*, *intArg2*, and *intArg3* parameters allow a CPU to announce the method by which it is to be notified of input packets which have been queued to it.

The *ticksPerBeat* parameter specifies the frequency of the shared memory anchor's heartbeat. The frequency is expressed in terms of the number of CPU ticks on the local CPU corresponding to one heartbeat period.

If *numLoan* is non-zero, it specifies the number of shared memory packets available to be loaned out.

RETURNS OK or ERROR.

SEE ALSO *if_sm*

smMemAddToPool()

NAME *smMemAddToPool()* – add memory to the shared memory system partition (VxMP Opt.)

SYNOPSIS

```
STATUS smMemAddToPool
(
    char *   pPool, /* pointer to memory pool */
    unsigned poolSize /* block size in bytes */
)
```

DESCRIPTION This routine adds memory to the shared memory system partition after the initial allocation of memory. The memory added need not be contiguous with memory previously assigned, but it must be in the same address space.

pPool is the global address of shared memory added to the partition. The memory area pointed to by *pPool* must be in the same address space as the shared memory anchor and shared memory pool.

poolSize is the size in bytes of shared memory added to the partition.

AVAILABILITY This routine is distributed as a component of the unbundled shared memory objects support option, VxMP.

RETURNS OK, or ERROR if access to the shared memory system partition fails.

ERRNO S_smObjLib_LOCK_TIMEOUT

SEE ALSO smMemLib

smMemCalloc()

NAME *smMemCalloc()* – allocate memory for an array from the shared memory system partition (VxMP Opt.)

SYNOPSIS

```
void * smMemCalloc
(
    int elemNum, /* number of elements */
    int elemSize /* size of elements */
)
```

DESCRIPTION This routine allocates a block of memory for an array that contains *elemNum* elements of size *elemSize* from the shared memory system partition. The return value is the local address of the allocated shared memory block.

AVAILABILITY This routine is distributed as a component of the unbundled shared memory objects support option, VxMP.

RETURNS A pointer to the block, or NULL if the memory cannot be allocated.

ERRNO S_memLib_NOT_ENOUGH_MEMORY
S_smObjLib_LOCK_TIMEOUT

SEE ALSO smMemLib

smMemFindMax()

NAME *smMemFindMax()* – find the largest free block in the shared memory system partition (VxMP Opt.)

SYNOPSIS

```
int smMemFindMax (void)
```

| | |
|---------------------|-------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | This routine searches for the largest block in the shared memory system partition free list and returns its size. |
| AVAILABILITY | This routine is distributed as a component of the unbundled shared memory objects support option, VxMP. |
| RETURNS | The size (in bytes) of the largest available block, or ERROR if the attempt to access the partition fails. |
| ERRNO | S_smObjLib_LOCK_TIMEOUT |
| SEE ALSO | smMemLib |

smMemFree()

| | |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>smMemFree()</i> – free a shared memory system partition block of memory (VxMP Opt.) |
| SYNOPSIS | <pre>STATUS smMemFree (void * ptr /* pointer to block of memory to be freed */)</pre> |
| DESCRIPTION | This routine takes a block of memory previously allocated with <i>smMemMalloc()</i> or <i>smMemCalloc()</i> and returns it to the free shared memory system pool. It is an error to free a block of memory that was not previously allocated. |
| AVAILABILITY | This routine is distributed as a component of the unbundled shared memory objects support option, VxMP. |
| RETURNS | OK, or ERROR if the block is invalid. |
| ERRNO | S_memLib_BLOCK_ERROR S_smObjLib_LOCK_TIMEOUT |
| SEE ALSO | smMemLib, <i>smMemMalloc()</i> , <i>smMemCalloc()</i> |

smMemMalloc()

| | |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>smMemMalloc()</i> – allocate a block of memory from the shared memory system partition (VxMP Opt.) |
| SYNOPSIS | <pre>void * smMemMalloc (unsigned nBytes /* number of bytes to allocate */)</pre> |
| DESCRIPTION | This routine allocates a block of memory from the shared memory system partition whose size is equal to or greater than <i>nBytes</i> . The return value is the local address of the allocated shared memory block. |
| AVAILABILITY | This routine is distributed as a component of the unbundled shared memory objects support option, VxMP. |
| RETURNS | A pointer to the block, or NULL if the memory cannot be allocated. |
| ERRNO | S_memLib_NOT_ENOUGH_MEMORY S_smObjLib_LOCK_TIMEOUT |
| SEE ALSO | smMemLib |

smMemOptionsSet()

| | |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>smMemOptionsSet()</i> – set the debug options for the shared memory system partition (VxMP Opt.) |
| SYNOPSIS | <pre>STATUS smMemOptionsSet (unsigned options /* options for system partition */)</pre> |
| DESCRIPTION | This routine sets the debug options for the shared system memory partition. Two kinds of errors are detected: attempts to allocate more memory than is available, and bad blocks found when memory is freed or reallocated. In both cases, the following options can be selected for actions to be taken when an error is detected: (1) return the error status, (2) log an error message and return the error status, or (3) log an error message and suspend |

the calling task. These options are discussed in detail in the library manual entry for **smMemLib**.

| | |
|---------------------|---------------------------------------------------------------------------------------------------------|
| AVAILABILITY | This routine is distributed as a component of the unbundled shared memory objects support option, VxMP. |
| RETURNS | OK or ERROR. |
| ERRNO | S_smObjLib_LOCK_TIMEOUT |
| SEE ALSO | smMemLib |

smMemRealloc()

| | |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>smMemRealloc()</i> – reallocate a block of memory from the shared memory system partition (VxMP Opt.) |
| SYNOPSIS | <pre>void * smMemRealloc (void * pBlock, /* block to be reallocated */ unsigned newSize /* new block size */)</pre> |
| DESCRIPTION | This routine changes the size of a specified block and returns a pointer to the new block of shared memory. The contents that fit inside the new size (or old size, if smaller) remain unchanged. The return value is the local address of the reallocated shared memory block. |
| AVAILABILITY | This routine is distributed as a component of the unbundled shared memory objects support option, VxMP. |
| RETURNS | A pointer to the new block of memory, or NULL if the reallocation cannot be completed. |
| ERRNO | S_memLib_NOT_ENOUGH_MEMORY S_memLib_BLOCK_ERROR S_smObjLib_LOCK_TIMEOUT |
| SEE ALSO | smMemLib |

smMemShow()

NAME `smMemShow()` – show the shared memory system partition blocks and statistics (VxMP Opt.)

SYNOPSIS

```
void smMemShow
(
    int type /* 0 = statistics, 1 = statistics & list */
)
```

DESCRIPTION This routine displays the total amount of free space in the shared memory system partition, including the number of blocks, the average block size, and the maximum block size. It also shows the number of blocks currently allocated, and the average allocated block size.

If *type* is 1, it displays a list of all the blocks in the free list of the shared memory system partition.

WARNING This routine locks access to the shared memory system partition while displaying the information. This can compromise the access time to the partition from other CPUs in the system. Generally, this routine is used for debugging purposes only.

EXAMPLE

```
-> smMemShow 1
FREE LIST:
  num   addr       size
  ----  -
   1   0x4ffef0    264
   2   0x4fef18   1700
SUMMARY:
  status      bytes   blocks  ave block max block
  -----
  current
    free     1964     2       982     1700
    alloc    2356     1      2356      -
  cumulative
    alloc    2620     2      1310      -
value = 0 = 0x0
```

AVAILABILITY This routine is distributed as a component of the unbundled shared memory objects support option, VxMP.

RETURNS N/A

smNameAdd()

| | | | | | | | | | | | | | | | | |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|---|-------------------------|------------|---|---------------------------|------------|---|----------------------|--------------|---|-------------------------|------------|---|-------------------------------|
| NAME | <i>smNameAdd()</i> – add a name to the shared memory name database (VxMP Opt.) | | | | | | | | | | | | | | | |
| SYNOPSIS | <pre>STATUS smNameAdd (char * name, /* name string to enter in database */ void * value, /* value associated with name */ int type /* type associated with name */)</pre> | | | | | | | | | | | | | | | |
| DESCRIPTION | <p>This routine adds a name of specified object type and value to the shared memory objects name database.</p> <p>The <i>name</i> parameter is an arbitrary null-terminated string with a maximum of 20 characters, including EOS.</p> <p>By convention, <i>type</i> values of less than 0x1000 are reserved by VxWorks; all other values are user definable. The following types are predefined in smNameLib.h :</p> <table><tr><td>T_SM_SEM_B</td><td>0</td><td>shared binary semaphore</td></tr><tr><td>T_SM_SEM_C</td><td>1</td><td>shared counting semaphore</td></tr><tr><td>T_SM_MSG_Q</td><td>2</td><td>shared message queue</td></tr><tr><td>T_SM_PART_ID</td><td>3</td><td>shared memory Partition</td></tr><tr><td>T_SM_BLOCK</td><td>4</td><td>shared memory allocated block</td></tr></table> <p>A name can be entered only once in the database, but there can be more than one name associated with an object ID.</p> | T_SM_SEM_B | 0 | shared binary semaphore | T_SM_SEM_C | 1 | shared counting semaphore | T_SM_MSG_Q | 2 | shared message queue | T_SM_PART_ID | 3 | shared memory Partition | T_SM_BLOCK | 4 | shared memory allocated block |
| T_SM_SEM_B | 0 | shared binary semaphore | | | | | | | | | | | | | | |
| T_SM_SEM_C | 1 | shared counting semaphore | | | | | | | | | | | | | | |
| T_SM_MSG_Q | 2 | shared message queue | | | | | | | | | | | | | | |
| T_SM_PART_ID | 3 | shared memory Partition | | | | | | | | | | | | | | |
| T_SM_BLOCK | 4 | shared memory allocated block | | | | | | | | | | | | | | |
| AVAILABILITY | This routine is distributed as a component of the unbundled shared memory objects support option, VxMP. | | | | | | | | | | | | | | | |
| RETURNS | OK, or ERROR if there is insufficient memory for <i>name</i> to be allocated, if <i>name</i> is already in the database, or if the database is already full. | | | | | | | | | | | | | | | |
| ERRNO | <pre>S_smNameLib_NOT_INITIALIZED S_smNameLib_NAME_TOO_LONG S_smNameLib_NAME_ALREADY_EXIST S_smNameLib_DATABASE_FULL S_smObjLib_LOCK_TIMEOUT</pre> | | | | | | | | | | | | | | | |
| SEE ALSO | smNameLib , smNameShow | | | | | | | | | | | | | | | |

smNameFind()

smNameFind()

| | |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>smNameFind()</i> – look up a shared memory object by name (VxMP Opt.) |
| SYNOPSIS | <pre> STATUS smNameFind (char * name, /* name to search for */ void * * pValue, /* pointer where to return value */ int * pType, /* pointer where to return object type */ int waitType /* NO_WAIT or WAIT_FOREVER */) </pre> |
| DESCRIPTION | <p>This routine searches the shared memory objects name database for an object matching a specified <i>name</i>. If the object is found, its value and type are copied to the addresses pointed to by <i>pValue</i> and <i>pType</i>. The value of <i>waitType</i> can be one of the following:</p> <p>NO_WAIT (0) The call returns immediately, even if <i>name</i> is not in the database.</p> <p>WAIT_FOREVER (-1) The call returns only when <i>name</i> is available in the database. If <i>name</i> is not already in, the database is scanned periodically as the routine waits for <i>name</i> to be entered.</p> |
| AVAILABILITY | This routine is distributed as a component of the unbundled shared memory objects support option, VxMP. |
| RETURNS | OK, or ERROR if the object is not found, if <i>name</i> is too long, or the wait type is invalid. |
| ERRNO | <p>S_smNameLib_NOT_INITIALIZED S_smNameLib_NAME_TOO_LONG S_smNameLib_NAME_NOT_FOUND S_smNameLib_INVALID_WAIT_TYPE S_smObjLib_LOCK_TIMEOUT</p> |
| SEE ALSO | <i>smNameLib</i> , <i>smNameShow</i> |

smNameFindByValue()

| | |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>smNameFindByValue()</i> – look up a shared memory object by value (VxMP Opt.) |
| SYNOPSIS | <pre> STATUS smNameFindByValue (void * value, /* value to search for */ char * name, /* pointer where to return name */ int * pType, /* pointer where to return object type */ int waitType /* NO_WAIT or WAIT_FOREVER */) </pre> |
| DESCRIPTION | <p>This routine searches the shared memory name database for an object matching a specified value. If the object is found, its name and type are copied to the addresses pointed to by <i>name</i> and <i>pType</i>. The value of <i>waitType</i> can be one of the following:</p> <p>NO_WAIT (0) The call returns immediately, even if the object value is not in the database.</p> <p>WAIT_FOREVER (-1) The call returns only when the object value is available in the database.</p> |
| AVAILABILITY | This routine is distributed as a component of the unbundled shared memory objects support option, VxMP. |
| RETURNS | OK, or ERROR if <i>value</i> is not found or if the wait type is invalid. |
| ERRNO | <p>S_smNameLib_NOT_INITIALIZED S_smNameLib_VALUE_NOT_FOUND S_smNameLib_INVALID_WAIT_TYPE S_smObjLib_LOCK_TIMEOUT</p> |
| SEE ALSO | <i>smNameLib</i> , <i>smNameShow</i> |

smNameRemove()

| | |
|---------------------|-------------------------------------------------------------------------------------------------------------------|
| NAME | <i>smNameRemove()</i> – remove an object from the shared memory objects name database (VxMP Opt.) |
| SYNOPSIS | <pre>STATUS smNameRemove (char * name /* name of object to remove */)</pre> |
| DESCRIPTION | This routine removes an object called <i>name</i> from the shared memory objects name database. |
| AVAILABILITY | This routine is distributed as a component of the unbundled shared memory objects support option, VxMP. |
| RETURNS | OK, or ERROR if the object name is not in the database or if <i>name</i> is too long. |
| ERRNO | S_smNameLib_NOT_INITIALIZED S_smNameLib_NAME_TOO_LONG S_smNameLib_NAME_NOT_FOUND S_smObjLib_LOCK_TIMEOUT |
| SEE ALSO | smNameLib, smNameShow |

smNameShow()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>smNameShow()</i> – show the contents of the shared memory objects name database (VxMP Opt.) |
| SYNOPSIS | <pre>STATUS smNameShow (int level /* information level */)</pre> |
| DESCRIPTION | This routine displays the names, values, and types of objects stored in the shared memory objects name database. Predefined types are shown, using their ASCII representations; all other types are printed in hexadecimal. |

The *level* parameter defines the level of database information displayed. If *level* is 0, only statistics on the database contents are displayed. If *level* is greater than 0, then both statistics and database contents are displayed.

WARNING This routine locks access to the shared memory objects name database while displaying its contents. This can compromise the access time to the name database from other CPUs in the system. Generally, this routine is used for debugging purposes only.

EXAMPLE

```
-> smNameShow
Names in Database Max : 30 Current : 6 Free : 24
-> smNameShow 1
Names in Database Max : 30 Current : 6 Free : 24
Name                Value                Type
-----
inputImage           0x802340             SM_MEM_BLOCK
ouputImage           0x806340             SM_MEM_BLOCK
imagePool            0x802001             SM_MEM_PART
imageInSem           0x8e0001             SM_SEM_B
imageOutSem          0x8e0101             SM_SEM_C
actionQ              0x8e0201             SM_MSG_Q
userObject           0x8e0400             0x1b0
```

AVAILABILITY This routine is distributed as a component of the unbundled shared memory objects support option, VxMP.

RETURNS OK, or ERROR if the name facility is not initialized.

ERRNO S_smNameLib_NOT_INITIALIZED
S_smObjLib_LOCK_TIMEOUT

SEE ALSO smNameShow, smNameLib

smNetAttach()

NAME *smNetAttach()* – attach the shared memory network interface

SYNOPSIS

```
STATUS smNetAttach
(
    int          unit,          /* interface unit number */
    SM_ANCHOR * pAnchor,       /* addr of anchor */
    int          maxInputPkts, /* max queued packets */
    int          intType,      /* interrupt method */
```

smNetInetGet()

```

    int          intArg1,      /* interrupt argument #1 */
    int          intArg2,      /* interrupt argument #2 */
    int          intArg3      /* interrupt argument #3 */
)

```

DESCRIPTION This routine attaches the shared memory interface to the network. It is called once by each CPU on the shared memory network. The *unit* parameter specifies the backplane unit number.

The *pAnchor* parameter is the local address by which the local CPU may access the shared memory anchor.

The *maxInputPkts* parameter specifies the maximum number of incoming shared memory packets which may be queued to this CPU at one time.

The *intType*, *intArg1*, *intArg2*, and *intArg3* parameters allow a CPU to announce the method by which it is to be notified of input packets which have been queued to it.

RETURNS OK, or ERROR if the shared memory interface cannot be attached.

SEE ALSO smNetLib

smNetInetGet()

NAME *smNetInetGet()* – get an address associated with a shared memory network interface

SYNOPSIS

```

STATUS smNetInetGet
(
    char * smName, /* device name */
    char * smInet, /* return inet */
    int   cpuNum  /* cpu number */
)

```

DESCRIPTION This routine returns the Internet address in *smInet* for the CPU specified by *cpuNum* on the shared memory network specified by *smName*. If *cpuNum* is NONE (-1), this routine returns information about the local (calling) CPU.

This routine can only be called after a call to *smNetAttach()*. It will block if the shared memory region has not yet been initialized.

This routine is only applicable if sequential addressing is being used over the backplane.

RETURNS OK, or ERROR if the Internet address cannot be found.

SEE ALSO smNetLib

smNetInit()

NAME *smNetInit()* – initialize the shared memory network driver

SYNOPSIS

```
STATUS smNetInit
(
    SM_ANCHOR * pAnchor,    /* local addr of anchor */
    char *      pMem,      /* local addr of shared memory */
    int         memSize,   /* size of shared memory */
    BOOL        tasType,   /* TRUE = hardware supports TAS */
    int         cpuMax,    /* max numbers of cpus */
    int         maxPktBytes, /* size of data packets */
    u_long      startAddr /* beginning address */
)
```

DESCRIPTION This routine is called once by the backplane master. It sets up and initializes the shared memory region of the shared memory network and starts the shared memory heartbeat. The *pAnchor* parameter is the local memory address by which the master CPU accesses the shared memory anchor. *pMem* contains either the local address of shared memory or the value NONE (-1), which implies that shared memory is to be allocated dynamically. *memSize* is the size, in bytes, of the shared memory region.

The *tasType* parameter specifies the test-and-set operation to be used to obtain exclusive access to the shared data structures. It is preferable to use a genuine test-and-set instruction, if the hardware permits it. In this case, *tasType* should be **SM_TAS_HARD**. If any of the CPUs on the backplane network do not support the test-and-set instruction, *tasType* should be **SM_TAS_SOFT**.

The *maxCpus* parameter specifies the maximum number of CPUs that may use the shared memory region.

The *maxPktBytes* parameter specifies the size, in bytes, of the data buffer in shared memory packets. This is the largest amount of data that may be sent in a single packet. If this value is not an exact multiple of 4 bytes, it will be rounded up to the next multiple of 4.

The *startAddr* parameter is only applicable if sequential addressing is desired. If *startAddr* is non-zero, it specifies the starting address to use for sequential addressing on the backplane. If *startAddr* is zero, sequential addressing is disabled.

RETURNS OK, or ERROR if the shared memory network cannot be initialized.

SEE ALSO **smNetLib**

smNetShow()

NAME *smNetShow()* – show information about a shared memory network

SYNOPSIS

```
STATUS smNetShow
(
    char * ifName, /* backplane interface name (NULL == "sm0") */
    BOOL  zero     /* TRUE = zap totals */
)
```

DESCRIPTION This routine displays information about the different CPUs configured in a shared memory network specified by *ifName*. It prints error statistics and zeros these fields if *zero* is set to TRUE.

EXAMPLE

```
-> smNetShow
Anchor at 0x800000
heartbeat = 705, header at 0x800010, free pkts = 237.
cpu int type   arg1      arg2      arg3      queued pkts
-----
0  poll                0x0      0x0      0x0      0
1  poll                0x0      0x0      0x0      0
2  bus-int            0x3      0xc9     0x0      0
3  mbox-2             0x2d     0x8000   0x0      0
input packets = 192    output packets = 164
output errors = 0      collisions = 0
value = 1 = 0x1
```

RETURNS OK, or ERROR if there is a hardware setup problem or the routine cannot be initialized.

SEE ALSO *smNetShow*

smObjAttach()

NAME *smObjAttach()* – attach the calling CPU to the shared memory objects facility (VxMP Opt.)

SYNOPSIS

```
STATUS smObjAttach
(
    SM_OBJ_DESC * pSmObjDesc /* pointer to shared memory descriptor */
)
```

| | |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | <p>This routine "attaches" the calling CPU to the shared memory objects facility. The shared memory area is identified by the shared memory descriptor with an address specified by <i>pSmObjDesc</i>. The descriptor must already have been initialized by calling <i>smObjInit()</i>.</p> <p>This routine is called automatically when the configuration macro <code>INCLUDE_SM_OBJ</code> is defined.</p> <p>This routine will complete the attach process only if and when the shared memory has been initialized by the master CPU. If the shared memory is not recognized as active within the timeout period (10 minutes), this routine returns <code>ERROR</code>.</p> <p>The <i>smObjAttach()</i> routine connects the shared memory objects handler to the shared memory interrupt. Note that this interrupt may be shared between the shared memory network driver and the shared memory objects facility when both are used at the same time.</p> |
| WARNING | <p>Once a CPU has attached itself to the shared memory objects facility, it cannot be detached. Since the shared memory network driver and the shared memory objects facility use the same low-level attaching mechanism, a CPU cannot be detached from a shared memory network driver if the CPU also uses shared memory objects.</p> |
| AVAILABILITY | <p>This routine is distributed as a component of the unbundled shared memory objects support option, <code>VxMP</code>.</p> |
| RETURNS | <p>OK, or <code>ERROR</code> if the shared memory objects facility is not active or the number of CPUs exceeds the maximum.</p> |
| ERRNO | <p><code>S_smLib_INVALID_CPU_NUMBER</code></p> |
| SEE ALSO | <p><i>smObjLib</i>, <i>smObjSetup()</i>, <i>smObjInit()</i></p> |

smObjGlobalToLocal()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <p><i>smObjGlobalToLocal()</i> – convert a global address to a local address (<code>VxMP</code> Opt.)</p> |
| SYNOPSIS | <pre>void * smObjGlobalToLocal (void * globalAdrs /* global address to convert */)</pre> |
| DESCRIPTION | <p>This routine converts a global shared memory address <i>globalAdrs</i> to its corresponding local value. This routine does not verify that <i>globalAdrs</i> is really a valid global shared memory address.</p> |

smObjInit()

| | |
|---------------------|---------------------------------------------------------------------------------------------------------|
| AVAILABILITY | This routine is distributed as a component of the unbundled shared memory objects support option, VxMP. |
| RETURNS | The local shared memory address pointed to by <i>globalAdrs</i> . |
| SEE ALSO | smObjLib |

smObjInit()

NAME *smObjInit()* – initialize a shared memory objects descriptor (VxMP Opt.)

SYNOPSIS

```
void smObjInit
(
    SM_OBJ_DESC * pSmObjDesc, /* ptr to shared memory descriptor */
    SM_ANCHOR * anchorLocalAdrs, /* shared memory anchor local adrs */
    int ticksPerBeat, /* cpu ticks per heartbeat */
    int smObjMaxTries, /* max no. of tries to obtain spinLock */
    int intType, /* interrupt method */
    int intArg1, /* interrupt argument #1 */
    int intArg2, /* interrupt argument #2 */
    int intArg3, /* interrupt argument #3 */
)
```

DESCRIPTION This routine initializes a shared memory descriptor. The descriptor must already be allocated in the CPU's local memory. Once the descriptor has been initialized by this routine, the CPU may attach itself to the shared memory area by calling *smObjAttach()*.

This routine is called automatically when the configuration macro **INCLUDE_SM_OBJ** is defined.

Only the shared memory descriptor itself is modified by this routine. No structures in shared memory are affected.

Parameters:

pSmObjDesc

the address of the shared memory descriptor to be initialized; this structure must be allocated before *smObjInit()* is called.

anchorLocalAdrs

the memory address by which the local CPU may access the shared memory anchor. This address may vary among CPUs in the system because of address offsets (particularly if the anchor is located in one CPU's dual-ported memory).

cpuNum

the number to be used to identify this CPU during shared memory operations. CPUs are numbered starting with zero for the master CPU, up to 1 less than the maximum number of CPUs defined during the master CPU's *smObjSetup()* call. CPUs can attach in any order, regardless of their CPU number.

ticksPerBeat

specifies the frequency of the shared memory anchor's heartbeat. The frequency is expressed in terms of how many CPU ticks on the local CPU correspond to one heartbeat period.

smObjMaxTries

specifies the maximum number of tries to obtain access to an internal mutually exclusive data structure. Its default value is 100, but it can be set to a higher value for a heavily loaded system.

intType, intArg1, intArg2, and intArg3

allow a CPU to announce the method by which it is to be notified of shared memory events. See the manual entry for *if_sm* for a discussion about interrupt types and their associated parameters.

- AVAILABILITY** This routine is distributed as a component of the unbundled shared memory objects support option, VxMP.
- RETURNS** N/A
- SEE ALSO** *smObjLib, smObjSetup(), smObjAttach()*

smObjLibInit()

- NAME** *smObjLibInit()* – install the shared memory objects facility (VxMP Opt.)
- SYNOPSIS** `STATUS smObjLibInit (void)`
- DESCRIPTION** This routine installs the shared memory objects facility. It is called automatically when the configuration macro `INCLUDE_SM_OBJ` is defined.
- AVAILABILITY** This routine is distributed as a component of the unbundled shared memory objects support option, VxMP.
- RETURNS** OK, or ERROR if the shared memory objects facility has already been installed.
- SEE ALSO** *smObjLib*

smObjLocalToGlobal()

| | |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>smObjLocalToGlobal()</i> – convert a local address to a global address (VxMP Opt.) |
| SYNOPSIS | <pre>void * smObjLocalToGlobal (void * localAdrs /* local address to convert */)</pre> |
| DESCRIPTION | This routine converts a local shared memory address <i>localAdrs</i> to its corresponding global value. This routine does not verify that <i>localAdrs</i> is really a valid local shared memory address. |
| AVAILABILITY | This routine is distributed as a component of the unbundled shared memory objects support option, VxMP. |
| RETURNS | The global shared memory address pointed to by <i>localAdrs</i> . |
| SEE ALSO | smObjLib |

smObjSetup()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>smObjSetup()</i> – initialize the shared memory objects facility (VxMP Opt.) |
| SYNOPSIS | <pre>STATUS smObjSetup (SM_OBJ_PARAMS * smObjParams /* setup parameters */)</pre> |
| DESCRIPTION | <p>This routine initializes the shared memory objects facility by filling the shared memory header. It must be called only once by the shared memory master CPU (processor number 0). It is called automatically only by the master CPU, when the configuration macro <code>INCLUDE_SM_OBJ</code> is defined.</p> <p>Any CPU on the system backplane can use the shared memory objects facility; however, the facility must first be initialized on the master CPU. Then before other CPUs are attached to the shared memory area by <i>smObjAttach()</i>, each must initialize its own shared memory objects descriptor using <i>smObjInit()</i>. This mechanism is similar to the one used by the shared memory network driver.</p> |

The *smObjParams* parameter is a pointer to a structure containing the values used to describe the shared memory objects setup. This structure is defined as follows in *smObjLib.h*:

```
typedef struct sm_obj_params /* setup parameters */
{
    BOOL        allocatedPool; /* TRUE if shared memory pool is malloced */
    SM_ANCHOR * pAnchor;      /* shared memory anchor */
    char *      smObjFreeAdrs; /* start address of shared memory pool */
    int        smObjMemSize;  /* memory size reserved for shared memory */
    int        maxCpus;      /* max number of CPUs in the system */
    int        maxTasks;     /* max number of tasks using smObj */
    int        maxSems;      /* max number of shared semaphores */
    int        maxMsgQueues; /* max number of shared message queues */
    int        maxMemParts;  /* max number of shared memory partitions */
    int        maxNames;     /* max number of names of shared objects */
} SM_OBJ_PARAMS;
```

| | |
|---------------------|-------------------------------------------------------------------------------------------------------------------------|
| AVAILABILITY | This routine is distributed as a component of the unbundled shared memory objects support option, VxMP. |
| RETURNS | OK, or ERROR if the shared memory pool cannot hold all the requested objects or the number of CPUs exceeds the maximum. |
| ERRNO | S_smObjLib_TOO_MANY_CPU S_smObjLib_SHARED_MEM_TOO_SMALL |
| SEE ALSO | smObjLib, <i>smObjInit()</i> , <i>smObjAttach()</i> |

smObjShow()

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>smObjShow()</i> – display the current status of shared memory objects (VxMP Opt.) |
| SYNOPSIS | STATUS <i>smObjShow</i> () |
| DESCRIPTION | This routine displays useful information about the current status of shared memory objects facilities. |
| WARNING | The information returned by this routine is not static and may be obsolete by the time it is examined. This information is generally used for debugging purposes only. |
| EXAMPLE | -> <i>smObjShow</i> Shared Mem Anchor Local Addr: 0x600. |

```
Shared Mem Hdr Local Addr:  0xb1514.  
Attached CPU :              5  
Max Tries to Take Lock:    1  
Shared Object Type      Current  Maximum  Available  
-----  
Tasks                   1      20      19  
Binary Semaphores       8      30      20  
Counting Semaphores     2      30      20  
Messages Queues         3      10      7  
Memory Partitions       1       4      3  
Names in Database      16     100     84
```

- AVAILABILITY** This routine is distributed as a component of the unbundled shared memory objects support option, VxMP.
- RETURNS** OK, or ERROR if no shared memory objects are initialized.

- SEE ALSO** **smObjShow, smObjLib**

smObjTimeoutLogEnable()

- NAME** *smObjTimeoutLogEnable()* – enable/disable logging of failed attempts to take a spin-lock (VxMP Opt.)
- SYNOPSIS**
- ```
void smObjTimeoutLogEnable
(
 BOOL timeoutLogEnable /* TRUE to enable, FALSE to disable */
)
```
- DESCRIPTION** This routine enables or disables the printing of a message when an attempt to take a shared memory spin-lock fails.  
By default, message logging is enabled.
- AVAILABILITY** This routine is distributed as a component of the unbundled shared memory objects support option, VxMP.
- RETURNS** N/A
- SEE ALSO** **smObjLib**

---

## ***sn83932EndLoad()***

- NAME** *sn83932EndLoad()* – initialize the driver and device
- SYNOPSIS**
- ```
END_OBJ * sn83932EndLoad
(
    char * initString /* String to be parse by the driver. */
)
```
- DESCRIPTION** This routine initializes the driver and the device to the operational state. All of the device specific parameters are passed in the *initString* parameter. This string must be of the format:
- unit_number:device_reg_addr:ivec*
- These parameters are all individually described in the *sn83932End* man page.
- RETURNS** An END object pointer or NULL on error.
- SEE ALSO** *sn83932End*

snattach()

- NAME** *snattach()* – publish the **sn** network interface and initialize the driver and device
- SYNOPSIS**
- ```
STATUS snattach
(
 int unit, /* unit number */
 char * pDevRegs, /* addr of device's regs */
 int ivec /* vector number */
)
```
- DESCRIPTION** This routine publishes the **sn** interface by filling in a network interface record and adding this record to the system list. It also initializes the driver and the device to the operational state.
- RETURNS** OK or ERROR.
- SEE ALSO** *if\_sn*

---

## **snmpMasterCleanup()**

**NAME** *snmpMasterCleanup()* – free up resources after a query times out

**SYNOPSIS**

```
void snmpMasterCleanup
(
 UINT_16_T reqid, /* request Id to track state block */
 UINT_16_T options /* as mentioned above */
)
```

**DESCRIPTION** If you use *snmpMasterHandlerAsync()*, the master agent calls this routine if the IPC layer determines that a timeout period for a query response has been exceeded. The *reqid* parameter is the same as the *requestId* value passed to the send routine. It is used to track the correct state block. The *options* parameter passes in a set of flags that control what actions the cleanup routine. Currently, there are three flags: SA\_CLEANUP\_INACTIVE, SA\_CLEANUP\_TIMEOUT, and SA\_CLEANUP\_CONTINUE. The continue and timeout flags should always be set. The inactive flag indicates that any objects associated with the subagent should be removed. Set this flag when the IPC layer determines that the subagent has stopped rather than timed out.

**RETURNS** N/A

**SEE ALSO** *subagentLib*

---

## **snmpMasterHandlerAsync()**

**NAME** *snmpMasterHandlerAsync()* – process messages from the subagent asynchronously

**SYNOPSIS**

```
void snmpMasterHandlerAsync
(
 OCTET_T * pMsg, /* pointer to the message */
 ALENGTH_T msgl, /* length of the message */
 IPCCOMP_T * pIpcComp, /* completion routine */
 IPCSEND_AS_T * pIpcSend, /* send routine */
 IPCRCV_T * pIpcRcv, /* receive routine */
 IPCFREE_T * pIpcFree, /* free routine */
 IPCAYT_T * pIpcAyt, /* status check routine */
 PTR_T ipchandle, /* ipchandle for the IPC scheme used */
 PTR_T user_priv /* MIB tree identifier */
)
```

**DESCRIPTION**

This function provides support for an asynchronous communication scheme between the master agent and its subagents. The shipped version of WindNet SNMP does not call this function. Instead, it calls *snmpMasterHandlerWR()*, a function that supports a synchronous communication scheme. If you want master agents and subagents to use an asynchronous communication scheme, you must rewrite *snmpQueMonitor()* to call *snmpMasterHandlerAsync()* instead of *snmpMasterHandlerWR()*. In addition, because *snmpMasterHandlerAsync()* does not return a function value, you will need to remove the *snmpQueMonitor()* code that responded to the *snmpMasterHandlerWR()* function value. The functionality handled by the removed code should instead be implemented in the function referenced by the *ipcComp* parameter. Use the parameters as follows:

*pMsg*

Expects a pointer to an **EBUFFER\_T** structure containing the data part of the message from the subagent. The message shows up on the queue as an **SA\_MESSAGE\_T** structure. The message expected by this parameter is contained in the **mesg** member of this structure. To extract this pointer, use **EbufferStart** macro defined in **buffer.h**.

*msgl*

Expects the length of the message referenced in *pMsg*. To retrieve this length value, use the **EBufferUsed** macro defined in **buffer.h**.

*pIpcComp*

Expects a pointer to the completion function, which must be of the form:

```
void masterIpcComp
(
 OCTET_T opcode, /* this specifies what needs to be done */
 EBUFFER_T * ebuf, /* reply message to be sent */
 VBL_T * vblst, /* list of varbinds that the message contained */
 PTR_T ipchandle /* subagent address */
)
```

The master agent executes this function upon completing processing for an unsolicited control message from a subagent (primarily registration requests, although a trap from the subagent will eventually find its way to this function). Your *masterIpcComp()* should be able handle things such as letting the subagent know the completion status of message it sent to the master agent.

For a registration routine, it must send the message in *ebuf* back to the subagent. This message contains the group ID of the MIB variables added to the master agent's MIB tree. The subagent needs this ID to make a deregistration request.

If you decide to support traps from subagents, this function must be able to forward the varbind list in *vblst* to the SNMP manager. In addition, it is your responsibility to acquire any values not specified in *vblst* and include it in the message you send the to the SNMP manager. Use the *opcode* to know when you are handling the completion processing for a registration request, a deregistration request, or a trap from a subagent.

For an example of an IPC completion routine, see *masterIpcComp()* defined in **masterIoLib.c**.

*pIpcSend*

Expects a pointer to the function that method routines should use to send messages to the subagent. This function must be of the form:

```
INT_32_T masterIpcSend
(
 EBUFFER_T * pBuf, /* message to be sent */
 PTR_T ipchandle /* address of subagent */
 UINT_16_T reqid /* ID for request sent */
)
```

To make the communication between the master agent and subagent asynchronous, this send routine should send the message to the subagent and return. Eventually, a response shows up on the master agent's local queue, or the query times out. How you process a query response or a query time out is almost entirely up to you.

To process a query response, you must call *snmpMasterQueryHandler()*. This function will handle the details of integrating the message from the subagent into a message to the SNMP manager.

To clean up after a send that times out, you must call *snmpMasterCleanup()*. The specifics of the mechanism you use are up to you, but you will likely need to integrate the mechanism with your *masterIpcSend()* routine. That is because this function gets the request ID that you will need for clean up. The request ID is a number generated internally to the SNMP master agent. It passes this value into your *masterIpcSend()* using the *reqid* parameter. To clean up after a send that times out, you submit the *reqid* in a call to *snmpMasterCleanup()*.

For an example of an *masterIpcSend()*, see the *masterIpcSend()* defined in **masterIoLib.c**.

*pIpcRcv*

This parameter is not used by *snmpMasterHandlerAsync()* and so should be null. It is included to maintain parallelism with *snmpMasterHandlerWR()*.

*pIpcFree*

Expects a pointer to a function of the form:

```
void masterIpcFree (PTR_T ipchandle)
```

The master agent uses this function to free any resources it might have allocated to maintain the IPC link with the subagent. The master agent calls this function when a subagent deregisters.

*pIpcAyt*

Expects a pointer to the function the master agent can use to test the connection with the subagent. This function must be of the form:

```
INT_32_T masterIpcAyt (PTR_T ipchandle)
```

For an example of such a function, see the *masterIpcAyt()* defined in **masterIoLib.c**.

*ipchandle*

Expects a pointer to the IPC handle used to access the subagent that sent this message. In the shipped implementation, this is a pointer to a message queue.

*user\_priv*

Expects a pointer to the MIB tree from which registration and deregistration requests want to add or delete objects or instances. If this pointer is NULL, the default MIB tree specified by *mib\_root\_node* is used.

**RETURNS** N/A

**SEE ALSO** **subagentLib**

## ***snmpMasterHandlerWR()***

**NAME** *snmpMasterHandlerWR()* – synchronous version of *snmpMasterHandlerAsync()*

**SYNOPSIS**

```
INT_32_T snmpMasterHandlerWR
(
 OCTET_T * pMsg, /* pointer to the message */
 ALENGTH_T msgl, /* length of the message */
 IPCSEND_T * pIpcSend, /* send routine */
 IPCRCV_T * pIpcRcv, /* receive routine */
 IPCFREE_T * pIpcFree, /* free routine */
 IPCAYT_T * pIpcAyt, /* status Check Routine */
 PTR_T ipchandle, /* ipchandle for the IPC scheme used */
 EBUFFER_T * pBuf, /* buffer to place reply in */
 VBL_T * pVblist, /* place to put varbinds */
 PTR_T user_priv /* MIB tree identifier */
)
```

**DESCRIPTION**

This function is called to process the control messages received from subagents when the communication method between master and subagent is synchronous.

To process a registration request, this function extracts the objects from the message and adds them as a group to the master agent's MIB tree. The actual get, test, and set methods for these objects reside in the subagent. To set up local methods for these routines, *snmpMasterHandlerAsync()* uses the function referenced in *pIpcSend* and *pIpcRcv*.

The methods local to the master agent use *pIpcSend* to send queries to the subagent which locally executes the actual method routine for the object. The subagent then transmits the results back to the master agent's public queue. When the function monitoring this queue

sees the query response, it transfers the message to the master agent's local queue where the *pIpcRcv* function is waiting for the response.

To process a deregistration request, this function extracts a group ID from the message and removes that group of objects from the master agent's MIB tree. It also executes the function in *pIpcFree* to free any resources allocated locally to maintain the IPC link with the deregistered subagent.

The *snmpMasterHandlerWR()* routine returns information using the output parameters *pBuf* and *pVblist* and its function return value. If the returned function value indicates success, the master agent sends the message returned in *pBuf* to the subagent that sent the registration or deregistration request. If the returned value of this function indicates failure, the master agent silently drops the packet.

This function as has the ability to return an opcode value, although this functionality is unused in the shipped version of WindNet SNMP. In fact, if *snmpMasterHandlerWR()* were to return an opcode, the current implementation of the master agent would silently drop the packet. The possibility of returning an opcode is supported to make it possible for you to create subagents that send traps. In this case, *snmpMasterHandlerWR()* would return an opcode and a varbind list using the *pVblist* parameter. You could then rewrite *snmpQueMonitor()*, the master agent function that calls *snmpMasterHandlerWR()*, so that it responds appropriately to the returned opcode and forwards the contents of *pVblist* to the SNMP manager.

Use the *snmpMasterHandlerWR()* parameters as follows:

*pMsg*

Expects a pointer to an **EBUFFER\_T** structure containing the data part of the message from the subagent. The message shows up on the queue as an **SA\_MESSAGE\_T** structure. The message expected by this parameter is contained in the **msg** member of the **SA\_MESSAGE\_T** structure. To extract this pointer, you can use the **EbufferStart** macro defined in defined in **buffer.h**.

*msgl*

Expects the length of the message referenced in *pMsg*. To retrieve this length value, use the **EbufferUsed** macro defined in **buffer.h**.

*pIpcSend*

Expects a pointer to the function that method routines should use to send messages to the subagent. This function must be of the form:

```
INT_32_T masterIpcSend
(
 EBUFFER_T * pBuf, /* message to be sent */
 PTR_T ipchandle /* address of subagent */
)
```

If *snmpMasterHandlerWR()* is processing a registration request from the subagent, it associates this function pointer with the group of objects it adds to the master agent's MIB tree. The methods for those objects call this routine to send a message to the

subagent to make a test, get, or set query against those variables. After using this function to send the message, the master agent then calls the function referenced in *pIpcRcv*. The *pIpcRcv* function waits on a local queue for a response from the subagent. For an example of an *masterIpcSend()* routine, see the *masterIpcSend()* defined in **masterIoLib.c**.

*ipcRcv*

Expects a pointer to a function of the form:

```
INT_32_T masterIpcRcv
(
 EBUFFER_T * pBuf, /* buffer to receive message */
 PTR_T ipchandle /* address of subagent */
)
```

If *snmpMasterHandlerWR()* is processing a registration request from the subagent, it associates this function pointer with the group of objects it adds to the master agent's MIB tree. The methods for those objects call this routine to wait on a local queue for a response from the subagent. For an example of an *masterIpcRcv()*, see the *masterIpcRcv()* defined in **masterIoLib.c**.

*ipcFree*

Expects a pointer to a function of the form:

```
void masterIpcFree (PTR_T ipchandle)
```

The master agent uses this function to free any resources it allocated to maintain the IPC link with the subagent. The master agent calls this function when a subagent deregisters.

*pIpcAyt*

Expects a pointer to the function the master agent can use to test the connection with the subagent. This function must be of the form:

```
INT_32_T masterIpcAyt (PTR_T ipchandle)
```

For an example of such a function, see the *masterIpcAyt()* defined in **masterIoLib.c**.

*ipchandle*

Expects a pointer to the IPC handle used to access the subagent that sent this message. In the shipped implementation, this is a pointer to a message queue.

*pBuf*

Expects a pointer to a previously allocated **EBUFFER\_T**. This is an output parameter that *snmpMasterHandlerWR()* uses this to return a reply packet, if one is generated. For example, if *snmpMasterHandlerWR()* successfully processes a registration request, it writes a message to the **EBUFFER\_T** at *pBuf*. This message contains the group ID for the objects just added to the master agent's MIB tree. When control returns from *snmpMasterHandlerWR()*, you must transmit this message back to the subagent, which will store the group ID for use in a deregistration request. In the current implementation, *snmpQueMonitor()* already handles this for you.

*pVblist*

Expects a pointer to a previously allocated **VBL\_T**. The intended use of this parameter is to provide an output vehicle for the varbind list received in a trap message from a subagent. Because of the application-dependent nature of traps, the shipped implementation of **snmpQueMonitor()** just drops the packet. However, if you want to support traps from your subagents, you can modify **snmpQueMonitor()** to check the returned value of **snmpMasterHandlerWR()** to watch for a trap message. You can then use **snmpIoTrapSend()** to forward the trap message in *pVblist* to the SNMP manager.

*user\_priv*

Expects a pointer to the MIB tree from which registration and deregistration requests want to add or delete objects or instances. If this pointer is **NULL**, the default MIB tree specified by **mib\_root\_node** is used.

If the message is trap request, it is the responsibility of the user code to acquire any values not specified in the trap message and to send the trap to the manager.

**RETURNS**

The opcode from the decoded packet or 0 or -1. An returned value of 0 indicates an error for which you should just drop the packet. A return value of -1 indicates success.

If this function returns an opcode, a value from 1 to 127, the shipped implementation just drops the packet. However, to support traps from the subagent, you could modify **snmpQueMonitor()** to note a returned value of **SA\_TRAP\_REQUEST** and then forward the varbind list in *pVblist* to the SNMP manager.

**subagentLib**

---

## **snmpMasterQueryHandler()**

**NAME**

**snmpMasterQueryHandler()** – handles replies from the subagent

**SYNOPSIS**

```
UINT_16_T snmpMasterQueryHandler
(
 OCTET_T * pMsg, /* pointer to the packet */
 ALENGTH_T msgl, /* length of packet */
 int flag /* should be 1 */
)
```

**DESCRIPTION**

This routine is for use with **snmpMasterHandlerAsync()**. It handles the replies to queries generated by the method routines. It decodes the message and tries to integrate the response with an outstanding packet. The *pMsg* and *msgl* parameters are pointers to the message and the length respectively. The *flag* parameter specifies whether the continuation routines should be run. This should always be set to 1.

**RETURNS** The request ID if routine could decode the packet or 0 in case of error.

**SEE ALSO** `subagentLib`

---

## *snmpMonitorSpawn()*

**NAME** *snmpMonitorSpawn()* – spawn `tMonQue` to run *snmpQueueMonitor()*

**SYNOPSIS** `void snmpMonitorSpawn (void)`

**DESCRIPTION** This function spawns the `tMonQue` task to run *snmpQueueMonitor()* a function that waits on the message queue that subagents use to leave messages for the master agent. The *snmpQueueMonitor()* waits forever on the master agent's message queue. When message comes in, it is interpreted using an `SA_MESSAGE_T` structure, which is defined in `ipcLib.h` as:

```
typedef struct SA_MESSAGE_S
{
 int msgType;
 MSG_Q_ID saId;
 EBUFFER_T mesg;
} SA_MESSAGE_T;
```

A switch internal to *snmpQueueMonitor()* handles the message according to the value of the `msgType` member.

If the message type is `CALL_QUERY_HANDLER`, the message is a response to a query from the master agent. The buffer referenced in the `mesg` is then transferred to the local message queue monitored by `tSnmpd`, where a *masterIpcRcv()* routine is waiting for a query response from a subagent.

If the message type is `CALL_REG_HANDLER`, the message is a control message such as a registration request, a deregistration request, or a trap. To respond to such requests, *snmpQueueMonitor()* passes the buffer in `mesg` to *snmpMasterHandlerWR()*.

If the message in the buffer passed to *snmpMasterHandlerWR()* is not correctly formed, the returned function value indicates failure and *snmpQueueMonitor()* drops the packet.

If the buffer passed to *snmpMasterHandlerWR()* is a correctly formed registration request, *snmpMasterHandlerWR()* adds the specified objects to the master agent's MIB tree. If the buffer contains a correctly formed deregistration request, *snmpMasterHandlerWR()* removes the specified objects from the master agent's MIB tree. In both cases the returned value of *snmpMasterHandlerWR()* indicates success and its *rbuf* parameter contains a message that *snmpQueueMonitor()* forwards to the subagent that sent the message.

**snmpSaHandlerAsync()**

In the case of a successful registration request, the message sent to the subagent contains a group ID for the objects just added to the master agent's MIB tree. When the subagent deregisters itself, it includes this ID in its deregistration message to the master agent. It also uses this group ID when it must register instances of the object just registered.

If the buffer passed to *snmpMasterHandlerWR()* contains a trap, the returned function value is *SA\_TRAP\_REQUEST*, the value extracted from the **opcode2** member of the header associated with the message. The message itself (minus the header) is a varbind list. It is returned using the *vbl* parameter. The current implementation of *snmpQueMonitor()* just drops this message. However, you can rewrite *snmpQueMonitor()* to make a *snmpIoTrapSend()* that forwards the varbind list to the SNMP manager. Likewise, you can implement appropriate responses to other **opcode2** values. Currently, **subagent.h** defines symbolic constants for opcodes 1 through 12 (with opcode 11, *SA\_TRAP\_REQUEST*, reserved for trap requests). If necessary you are free to use the remaining opcodes for message types specific to your implementation.

If your transport needs require that you rewrite **masterIoLib** to use an IPC other than message queues, you might need to modify this function, which is called from *snmpIoMain()* just before a call to *snmpIoBody()*. For example, if you use sockets as your IPC between the SNMP master agent and its subagents, **tSnmpd** could monitor the socket connection with the SNMP manager as well as the socket connections with the SNMP subagents.

**ASYNCHRONOUS COMMUNICATION**

The shipped version of *snmpQueMonitor()* uses *snmpMasterHandlerWR()* and thus processes messages asynchronously. However, if necessary, you can rewrite *snmpQueMonitor()* to call *snmpMasterHandlerAsync()* instead. For more information on *snmpMasterHandlerAsync()*, see its reference entry.

**RETURNS** N/A

**SEE ALSO** **masterIoLib**

---

## *snmpSaHandlerAsync()*

**NAME** *snmpSaHandlerAsync()* – asynchronous message processing routine for the subagent

**SYNOPSIS**

```
void snmpSaHandlerAsync
(
 OCTET_T * pMsg, /* message from the master-agent */
 ALENGTH_T msglength, /* length of message in octets */
 PTR_T root, /* root of mib tree */
 SA_IO_COMPLETE_T * pIoComp, /* IO completion routine */

```

```

SA_ERR_COMPLETE_T * pErrComp, /* error completion routine */
SA_REG_COMPLETE_T * pRegComp, /* registration complete routine */
PTR_T cookie /* cookie */
)

```

**DESCRIPTION**

It decodes the message in *pMsg* and responds appropriately, which can include testing, getting, and setting variables. After the message is processed, *snmpSaHandlerAsync()* then calls whichever completion routine is appropriate.

*pMsg*

Expects pointer to an octet string containing the message from the master agent.

*msglength*

Expects the length of the message.

*root*

Expects a pointer to the root of the subagent's MIB tree. If *root* is NULL, the default **mib\_root\_node** is used.

*pIoComp*

Expects a pointer to the function *snmpSaHandlerAsync()* should call after it has processed the message from the master agent. This routine should be able to send a response to the master agent, if necessary. This function must handle the building, encoding, transmission of the response to the master agent. This function must be of the form:

```
void SA_IO_COMPLETE_T(PTR_T pkt, SA_HEADER_T *hdr_blk, PTR_T cookie)
```

When the subagent calls this routine, it uses the *pkt* parameter to pass in a pointer to the data to be sent to the master agent. It uses the *hdr\_blk* parameter to pass in a pointer to the header to be included with the packet. It uses the *cookie* parameter to pass in the *cookies* specified in the call to *snmpSaHandlerAsync()*. You can use this *cookie* to carry information specific to your environment and application.

*pErrComp*

Expects a pointer to the function *snmpSaHandlerAsync()* should call if it cannot generate an appropriate response to a message from the master agent. This function must be of the form:

```
void SA_ERR_COMPLETE_T(int error_code, PTR_T cookie)
```

The *error\_code* passes in one of the following error codes:

```

SA_GEN_ERROR
SA_UNKNOWN_VERSION
SA_UNKNOWN_OPCODE1
SA_UNKNOWN_OPCODE2
SA_UNKNOWN_ENCODING
SA_DECODE_FAILURE
SA_ENCODE_FAILURE
SA_UNKNOWN_NODE

```

***snmpSaHandlerCleanup()***

SA\_UNKNOWN\_TAG  
 SA\_UNKNOWN\_GRP  
 SA\_SHORT\_MSG  
 SA\_IPC\_ERROR  
 SA\_LOCK\_ERROR  
 SA\_NODE\_ERROR  
 SA\_MEMORY\_ERROR  
 SA\_UNSUPPORTED\_TYPE  
 SA\_NO\_SAVED\_PACKET

The *cookie* parameter passes in the *cookie* specified in the call to *snmpSaHandlerAsync()*. You can use this *cookie* to carry information specific to your environment and application.

*pRegComp*

Expects a pointer to the function *snmpSaHandlerAsync()* should call in response to a registration completion message from the master agent. If successful, this message should contain a group ID for the MIB variables that the registration request added to the master agent's MIB tree. The subagent needs this ID when it comes time to deregister and remove those variables from the master agent's MIB tree. This function must be of the form:

```
void SA_REG_COMPLETE_T (INT_32_T ecode, SA_HEADER_T *hdr_blk,
 VBL_T *vblp, PTR_T cookie)
```

This completion routine expects an error code in *ecode*, a header block in *hdr\_blk*, a list of nodes at *vblp*, and the *cookie* passed into the *snmpSaHandlerAsync()*.

*cookie*

Expects a pointer that you can use to pass data unchanged to the functions you specified in the *pIoComp*, *pErrComp*, and *pRegComp* functions.

**RETURNS** N/A

**SEE ALSO** [subagentLib](#)

---

## ***snmpSaHandlerCleanup()***

**NAME** *snmpSaHandlerCleanup()* – cleanup routine for subagent

**SYNOPSIS**

```
void snmpSaHandlerCleanup
(
 PTR_T pPkt, /* pointer to the packet */
 SA_HEADER_T * pHdr /* header block */
)
```

**DESCRIPTION** This routine is called by the IO completion routine if it detects an error. It either frees or arranges to free any resources that might have been allocated for processing a query from the master agent. The information at *pPkt* and *pHdr* is passed unchanged into the completion routine.

**RETURNS** N/A

**SEE ALSO** *subagentLib*

## *snmpSaHandlerContinue()*

**NAME** *snmpSaHandlerContinue()* – subagent continuation function

**SYNOPSIS**

```
void snmpSaHandlerContinue
(
 SNMP_PKT_T * pPkt /* pointer to the SNMP packet */
)
```

**DESCRIPTION** This routine is similar to *snmpdContinue()*. Method routines that do not complete their tasks before returning should arrange to have this routine called when the task is finished. This routine should not be called if you call *snmpSaHandlerWR()*. The *pPkt* parameter expects a pointer to the packet. If *SNMP\_CONTINUE\_REENTRANT* is installed, this routine will attempt to release the per-packet write lock.

**RETURNS** N/A

**SEE ALSO** *subagentLib*

## *snmpSaHandlerFinish()*

**NAME** *snmpSaHandlerFinish()* – encode packet for subagent IO completion

**SYNOPSIS**

```
INT_32_T snmpSaHandlerFinish
(
 PTR_T pkt, /* pointer to the packet */
 SA_HEADER_T * pHdr, /* header block */
 EBUFFER_T * pBuf /* buffer to place the result in */
)
```

- DESCRIPTION** This routine encodes the packet at *pkt* and the header block at *pHdr*. If *pBuf* is empty, this routine tries to allocate space. If it cannot or if the space provided is too small, an error is returned.
- RETURNS** 0 on success, or a non-zero value on failure.
- SEE ALSO** **subagentLib**

---

## **snmpSaHandlerWR()**

**NAME** *snmpSaHandlerWR()* – provide *snmpSaHandlerAsync()* functionality synchronously

**SYNOPSIS**

```
INT_32_T snmpSaHandlerWR
(
 OCTET_T * pMsg, /* message from the master-agent */
 ALENGTH_T msgl, /* length of message in octets */
 EBUFFER_T * pBuf, /* buffer to hold reply packet */
 SA_HEADER_T * pHdr, /* place for header structure */
 VBL_T * pVblist, /* place for vblist */
 PTR_T root /* root of mib tree */
)
```

**DESCRIPTION** This routine puts a synchronous shell around *snmpSaHandlerAsync()*. Like *snmpSaHandlerAsync()*, this function can decode a message from the master agent. If the message is a query against a variable in the subagent's MIB tree, *snmpSaHandlerWR()* processes the request and generates a response. However, *snmpSaHandlerWR()* does not handle the completion processing for the message that would have been handled by the *pIoComp*, *pErrComp*, and *pRegComp* routines specified as input to *snmpSaHandlerAsync()*.

Instead, it uses its returned function value to indicate that status of the message processing and uses *pBuf*, *pHdr*, and *pVblist* as output parameters if that status requires additional processing on your part. For example, if the message was a successfully processed query, the response data is included in *pVblist* and a header is included in *pHdr*, but that response is not yet encoded in a packet or transmitted back to the master agent. In *snmpSaHandlerAsync()*, all that would normally be handled in the *pIoComp* routine. Effectively, you must now call your *pIoComp* routine explicitly.

*pMsg*

Expects a pointer to the message, an octet string, from the master agent.

*msgl*

Expects the length of the message starting at *pMsg*.

*pBuf*

Expects a pointer to a previously allocated **EBUFFER\_T** into which this function can write a response, if any. In some cases (if **opcode1** is **SA\_QUERY\_REQUEST**), instead of indicating an error in the returned value of *snmpSaHandlerWR()*, the error is encoded into this message. This is done for errors more appropriately handled by the SNMP manager.

*pHdr*

Expects a pointer to a previously allocated **SA\_HEADER\_T** structure into which this function can write header block information, if necessary. If **hdr\_blk.sa\_error** is non-zero, other members might not contain valid data.

*pVblist*

Expects a pointer to a previously allocated **VBL\_T** structure into which this function can write the list of nodes found in the original message from the master agent.

*root*

Expects a pointer to the root of the subagent's MIB tree. If *root* is **NULL**, the default **mib\_root\_node** is used.

**RETURNS**

0 on success, or a positive value indicating an error. For return code values, see **subagent.h**. Using these values as a switch, you should call one of the functions you would have specified for *pIoComp*, *pErrComp*, or *pRegComp* in a call to *snmpSaHandlerAsync()*.

**SEE ALSO****subagentLib**

---

## **snmpSaInit()**

**NAME***snmpSaInit()* – initialize the subagent**SYNOPSIS**

```
PTR_T snmpSaInit
(
 PTR_T saId, /* ipchandle for socket/queue */
 PTR_T sa_root, /* pointer to mib root node */
 SA_REG_COMPLETE_T saRegComp /* registration complete routine */
)
```

**DESCRIPTION**

Call this routine to initialize an SNMP subagent. Internally, this routine creates an IPC mechanism for receiving messages from the master agent and then spawns a task to run *snmpSaMonitor()*, a function that monitors the IPC mechanism created by *snmpSaInit()*. As input, *snmpSaInit()* takes the parameters: *saId*, *sa\_root*, and *saRegComp*.

**snmpSubEncode( )***salD*

Expects a null. In most functions in this library, an *salD* parameter is a pointer to the IPC mechanism used to pass messages to the subagent. However, the IPC mechanism is first created internally to this function. Thus, this *salD* parameter is not actually used for input nor is it an output parameter. It is included for parallelism with other functions in this library.

*sa\_root*

This parameter provides a pointer to the MIB tree for this subagent.

*saRegComp*

Use this routine to pass in a pointer to the function that *snmpSaHandlerAsync( )* should execute in response to a registration status message from the master agent. If the registration was successful, the response contains a group ID for the MIB variables registered with the master agent. You will need this group ID when it comes time to deregister this SNMP subagent, or when you need to register instances of the object just registered.

Although this function sets up the IPC mechanism and spawns the task that is effectively the SNMP subagent, this routine does not actually register the subagent with the master agent. The details of how and when one does that are entirely dependent upon the nature of the system you are designing. Thus, no generic registration utility is provided. For more information on sending a registration request to the master agent, see the description of *hdrBlkBuild( )*.

**RETURNS** A pointer to the IPC mechanism created within this function, or NULL on failure.

**SEE ALSO** [saIoLib](#)

**snmpSubEncode( )**

**NAME** *snmpSubEncode( )* – encode a packet for transmission to master agent or subagent

**SYNOPSIS**

```

INT_32_T snmpSubEncode
(
 VBL_T * pVblist, /* varbindlist to be encoded */
 SA_HEADER_T * pHdr, /* header block structure */
 SA_DEMUX_T * pDemuxer, /* demuxer structure */
 EBUFFER_T * pBuf /* buffer to place result in */
)

```

**DESCRIPTION** This routine encodes a memory-resident varbind list. The result is a buffer containing a message ready for transmission. Most of the arguments are values to be encoded into the buffer.

*pVblist*

Expects a pointer to a **VBL\_T** structure containing the list of the varbinds to be encoded in the message. In a control message, the varbinds identify the nodes or instances to be added or removed from the master agents MIB tree. In a query message, the varbinds identify the variables to be gotten or set. In a trap message sent from a subagent to its master agent, the varbinds specify the objects to be sent in a trap message to the SNMP manager. A trap message from a subagent follows the SNMPv2 trap style. Thus, the first object in the list must always be **sysUpTime**. The second object must be a **snmpTrapOID.0** whose value is the administratively assigned name of the notification.

*pHdr*

Expects a pointer to a **SA\_HEADER\_T** structure containing all the items that go into the message header.

*pDemuxer*

Expects a pointer to an **SA\_DEMUX\_T** structure containing all the information the subagent might need to demux the packet. That is, to determine the time and space contexts for this request. In a v1 request, the string part of the demuxer is the community string and the object ID is unused. In a v2 request, the string is the local entity string from the context and the Object ID is the local time ID from the context.

*pBuf*

Expects a pointer to an **EBUFFER\_T** structure into which *snmpSubEncode()* can write the encoded packet. If *pBuf* references a previously allocated **EBUFFER\_T** structure, *snmpSubEncode()* uses that space. Otherwise, *snmpSubEncode()* tries to the necessary space.

**RETURNS** 0, if successful (that is, the structure at *pBuf* is ready for transmission); 1, if there is an illegal or unknown argument; 2, if there is insufficient buffer space at *pBuf* or space cannot be allocated.

## ***sntpTimeGet()***

**NAME** *sntpTimeGet()* – retrieve the current time from a remote source

**SYNOPSIS**

```
STATUS sntpTimeGet
(
 char * pServerAddr, /* server IP address or hostname */
 u_int timeout, /* timeout interval in ticks */
 struct timespec * pCurrTime /* storage for retrieved time value */
)
```

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | This routine stores the current time as reported by an SNTP/NTP server in the location indicated by <i>pCurrTime</i> . The reported time is first converted to the elapsed time since January 1, 1970, 00:00, GMT, which is the base value used by UNIX systems. If <i>pServerAddr</i> is NULL, the routine listens for messages sent by an SNTP/NTP server in broadcast mode. Otherwise, this routine sends a request to the specified SNTP/NTP server and extracts the reported time from the reply. In either case, an error is returned if no message is received within the interval specified by <i>timeout</i> . Typically, SNTP/NTP servers operating in broadcast mode send update messages every 64 to 1024 seconds. An infinite timeout value is specified by WAIT_FOREVER. |
| <b>RETURNS</b>     | OK, or ERROR if unsuccessful.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>ERRNO</b>       | S_sntpLib_INVALID_PARAMETER<br>S_sntpLib_INVALID_ADDRESS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SEE ALSO</b>    | sntpLib                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>NAME</b>        | <i>sntpClockSet()</i> – assign a routine to access the reference clock                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <pre>STATUS sntpClockSet (     FUNCPTR pClockHookRtn /* new interface to reference clock */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | <p>This routine installs a hook routine that is called to access the reference clock used by the SNTP server. This hook routine must use the following interface:</p> <pre>STATUS sntpClockHook (int request, void *pBuffer);</pre> <p>The hook routine should copy one of three settings used by the server to construct outgoing NTP messages into <i>pBuffer</i> according to the value of the <i>request</i> parameter. If the requested setting is available, the installed routine should return OK (or ERROR otherwise).</p> <p>This routine calls the given hook routine with the <i>request</i> parameter set to <b>SNTPS_ID</b> to get the 32-bit reference identifier in the format specified in RFC 1769. It also calls the hook routine with <i>request</i> set to <b>SNTPS_RESOLUTION</b> to retrieve a 32-bit value containing the clock resolution in nanoseconds. That value will be used to determine the 8-bit signed integer indicating the clock precision (according to the format specified in RFC 1769). Other library routines will set the <i>request</i> parameter to <b>SNTPS_TIME</b> to retrieve the current 64-bit NTP timestamp from <i>pBuffer</i> in host byte order. The routine</p> |

*sntpNsecToFraction()* will convert a value in nanoseconds to the format required for the NTP fractional part.

**RETURNS** OK or ERROR.

**ERRNO** N/A

## *sntpConfigSet()*

**NAME** *sntpConfigSet()* – change SNTP server broadcast settings

**SYNOPSIS**

```
STATUS sntpConfigSet
(
 int setting, /* configuration option to change */
 void * pValue /* new value for parameter */
)
```

**DESCRIPTION** This routine alters the configuration of the SNTP server when operating in broadcast mode. A *setting* value of `SNTPS_DELAY` interprets the contents of *pValue* as the new 16-bit broadcast interval. When *setting* equals `SNTPS_ADDRESS`, *pValue* should provide the string representation of an IP broadcast or multicast address (for example, "224.0.1.1"). Any changed settings will take effect after the current broadcast interval is completed and the corresponding NTP message is sent.

**RETURNS** OK or ERROR.

**ERRNO** `S_sntpLib_INVALID_PARAMETER`

**SEE ALSO** *sntpLib*

| <b>NAME</b>        | <b><i>sntpsNsecToFraction()</i></b> – convert portions of a second to NTP format                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <pre>ULONG sntpsNsecToFraction (     ULONG nsecs /* nanoseconds to convert to binary fraction */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | This routine is provided for convenience in fulfilling an <b>SNTPS_TIME</b> request to the clock hook. It converts a value in nanoseconds to the fractional part of the NTP timestamp format. The routine is not designed to convert non-normalized values greater than or equal to one second. Although the NTP time format provides a precision of about 200 pico-seconds, rounding errors in the conversion process decrease the accuracy as the input value increases. In the worst case, only the 24 most significant bits are valid, which reduces the precision to tenths of a micro-second. |
| <b>RETURNS</b>     | Value for NTP fractional part in host-byte order.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>ERRNO</b>       | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <b><i>so()</i></b> – single-step, but step over a subroutine                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <pre>STATUS so (     int task /* task to step; 0 = use default */ )</pre>                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | This routine single-steps a task that is stopped at a breakpoint. However, if the next instruction is a JSR or BSR, <b>so()</b> breaks at the instruction following the subroutine call instead. To execute, enter:<br><br>-> <b>so [task]</b><br><br>If <i>task</i> is omitted or zero, the last task referenced is assumed. |

---

## *socket()*

**NAME** *socket()* – open a socket

**SYNOPSIS**

```
int socket
(
 int domain, /* address family (for example, AF_INET) */
 int type, /* SOCK_STREAM, SOCK_DGRAM, or SOCK_RAW */
 int protocol /* socket protocol (usually 0) */
)
```

**DESCRIPTION** This routine opens a socket and returns a socket descriptor. The socket descriptor is passed to the other socket routines to identify the socket. The socket descriptor is a standard I/O system file descriptor (fd) and can be used with the *close()*, *read()*, *write()*, and *ioctl()* routines.

Available socket types include:

**SOCK\_STREAM**

Specifies a connection-based (stream) socket.

**SOCK\_DGRAM**

Specifies a datagram (UDP) socket.

**SOCK\_RAW**

Specifies a raw socket.

**RETURNS** A socket descriptor, or ERROR.

**SEE ALSO** *sockLib*

---

## *sp()*

**NAME** *sp()* – spawn a task with default parameters

**SYNOPSIS**

```
int sp
(
 FUNCPTR func, /* function to call */
 int arg1, /* first of nine args to pass to spawned task */
 int arg2,
 int arg3,
 int arg4,
 int arg5,
```

**sprintf()**

```

 int arg6,
 int arg7,
 int arg8,
 int arg9
)

```

**DESCRIPTION** This command spawns a specified function as a task with the following defaults:

priority:

100

stack size:

20,000 bytes

task ID:

highest not currently used

task options:

VX\_FP\_TASK – execute with floating-point coprocessor support.

task name:

A name of the form **tN** where N is an integer which increments as new tasks are spawned, e.g., **t1**, **t2**, **t3**, etc.

The task ID is displayed after the task is spawned.

This command is a short form of the underlying *taskSpawn()* routine, convenient for spawning tasks in which the default parameters are satisfactory. If the default parameters are unacceptable, *taskSpawn()* should be called directly.

**RETURNS** A task ID, or ERROR if the task cannot be spawned.

**SEE ALSO** **usrLib**, **taskLib**, *taskSpawn()*, *VxWorks Programmer's Guide: Target Shell*, **windsh**, *Tornado User's Guide: Shell*

---

**sprintf()**

**NAME** *sprintf()* – write a formatted string to a buffer (ANSI)

**SYNOPSIS**

```

int sprintf
(
 char * buffer, /* buffer to write to */
 const char * fmt /* format string */
)

```

|                    |                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | This routine copies a formatted string to a specified buffer, which is null-terminated. Its function and syntax are otherwise identical to <i>printf()</i> . |
| <b>RETURNS</b>     | The number of characters copied to <i>buffer</i> , not including the NULL terminator.                                                                        |

## *spy()*

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>spy()</i> – begin periodic task activity reports                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <pre>void spy (     int freq,          /* reporting freq in sec, 0 = default of 5 */     int ticksPerSec /* interrupt clock freq, 0 = default of 100 */ )</pre>                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>This routine collects task activity data and periodically runs <i>spyReport()</i>. Data is gathered <i>ticksPerSec</i> times per second, and a report is made every <i>freq</i> seconds. If <i>freq</i> is zero, it defaults to 5 seconds. If <i>ticksPerSec</i> is omitted or zero, it defaults to 100.</p> <p>This routine spawns <i>spyTask()</i> to do the actual reporting.</p> <p>It is not necessary to call <i>spyClkStart()</i> before running <i>spy()</i>.</p> |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SEE ALSO</b>    | <i>usrLib, spyLib, spyClkStart(), spyTask(), VxWorks Programmer's Guide: Target Shell</i>                                                                                                                                                                                                                                                                                                                                                                                    |

---

## *spyClkStart()*

|                 |                                                                                                     |
|-----------------|-----------------------------------------------------------------------------------------------------|
| <b>NAME</b>     | <i>spyClkStart()</i> – start collecting task activity data                                          |
| <b>SYNOPSIS</b> | <pre>STATUS spyClkStart (     int intsPerSec /* timer interrupt freq, 0 = default of 100 */ )</pre> |

## ***spyClkStop()***

- DESCRIPTION** This routine begins data collection by enabling the auxiliary clock interrupts at a frequency of *intsPerSec* interrupts per second. If *intsPerSec* is omitted or zero, the frequency will be 100. Data from previous collections is cleared.
- RETURNS** OK, or ERROR if the CPU has no auxiliary clock, or if task create and delete hooks cannot be installed.
- SEE ALSO** *usrLib*, *spyLib*, *sysAuxClkConnect()*, *VxWorks Programmer's Guide: Target Shell*

---

## ***spyClkStop()***

- NAME** *spyClkStop()* – stop collecting task activity data
- SYNOPSIS** `void spyClkStop (void)`
- DESCRIPTION** This routine disables the auxiliary clock interrupts. Data collected remains valid until the next *spyClkStart()* call.
- RETURNS** N/A
- SEE ALSO** *usrLib*, *spyLib*, *spyClkStart()*, *VxWorks Programmer's Guide: Target Shell*

---

## ***spyHelp()***

- NAME** *spyHelp()* – display task monitoring help menu
- SYNOPSIS** `void spyHelp (void)`
- DESCRIPTION** This routine displays a summary of *spyLib* utilities:
- |                                           |                                                                                     |
|-------------------------------------------|-------------------------------------------------------------------------------------|
| <code>spyHelp</code>                      | Print this list                                                                     |
| <code>spyClkStart [ticksPerSec]</code>    | Start task activity monitor running<br>at <code>ticksPerSec</code> ticks per second |
| <code>spyClkStop</code>                   | Stop collecting data                                                                |
| <code>spyReport</code>                    | Prints display of task activity<br>statistics                                       |
| <code>spyStop</code>                      | Stop collecting data and reports                                                    |
| <code>spy [freq[,ticksPerSec]]</code>     | Start <code>spyClkStart</code> and do a report<br>every <code>freq</code> seconds   |
| <code>ticksPerSec</code> defaults to 100. | <code>freq</code> defaults to 5 seconds.                                            |

**RETURNS** N/A

**SEE ALSO** **usrLib**, **spyLib**, *VxWorks Programmer's Guide: Target Shell*

---

## ***spyLibInit()***

**NAME** *spyLibInit()* – initialize task cpu utilization tool package

**SYNOPSIS** `void spyLibInit (void)`

**DESCRIPTION** This routine initializes the task cpu utilization tool package. If the configuration macro `INCLUDE_SPY` is defined, it is called by the root task, *usrRoot()*, in `usrConfig.c`.

**RETURNS** N/A

**SEE ALSO** **spyLib**, **usrLib**

---

## ***spyReport()***

**NAME** *spyReport()* – display task activity data

**SYNOPSIS** `void spyReport (void)`

**DESCRIPTION** This routine reports on data gathered at interrupt level for the amount of CPU time utilized by each task, the amount of time spent at interrupt level, the amount of time spent in the kernel, and the amount of idle time. Time is displayed in ticks and as a percentage, and the data is shown since both the last call to *spyClkStart()* and the last *spyReport()*. If no interrupts have occurred since the last *spyReport()*, nothing is displayed.

**RETURNS** N/A

**SEE ALSO** **usrLib**, **spyLib**, *spyClkStart()*, *VxWorks Programmer's Guide: Target Shell*

## **spyStop()**

|                    |                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>spyStop()</i> – stop spying and reporting                                                                             |
| <b>SYNOPSIS</b>    | <code>void spyStop (void)</code>                                                                                         |
| <b>DESCRIPTION</b> | This routine calls <i>spyClkStop()</i> . Any periodic reporting by <i>spyTask()</i> is terminated.                       |
| <b>RETURNS</b>     | N/A                                                                                                                      |
| <b>SEE ALSO</b>    | <i>usrLib</i> , <i>spyLib</i> , <i>spyClkStop()</i> , <i>spyTask()</i> , <i>VxWorks Programmer's Guide: Target Shell</i> |

## **spyTask()**

|                    |                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>spyTask()</i> – run periodic task activity reports                                                                                                                     |
| <b>SYNOPSIS</b>    | <pre>void spyTask (     int freq /* reporting frequency, in seconds */ )</pre>                                                                                            |
| <b>DESCRIPTION</b> | This routine is spawned as a task by <i>spy()</i> to provide periodic task activity reports. It prints a report, delays for the specified number of seconds, and repeats. |
| <b>RETURNS</b>     | N/A                                                                                                                                                                       |
| <b>SEE ALSO</b>    | <i>usrLib</i> , <i>spyLib</i> , <i>spy()</i> , <i>VxWorks Programmer's Guide: Target Shell</i>                                                                            |

---

## **sqrt()**

|                 |                                                                                   |
|-----------------|-----------------------------------------------------------------------------------|
| <b>NAME</b>     | <i>sqrt()</i> – compute a non-negative square root (ANSI)                         |
| <b>SYNOPSIS</b> | <pre>double sqrt (     double x /* value to compute the square root of */ )</pre> |

|                      |                                                                                                                                   |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b>   | This routine computes the non-negative square root of $x$ in double precision. A domain error occurs if the argument is negative. |
| <b>INCLUDE FILES</b> | <b>math.h</b>                                                                                                                     |
| <b>RETURNS</b>       | The double-precision square root of $x$ or 0 if $x$ is negative.                                                                  |
| <b>ERRNO</b>         | EDOM                                                                                                                              |
| <b>SEE ALSO</b>      | <b>ansiMath, mathALib</b>                                                                                                         |

## ***sqrtf()***

|                      |                                                                                  |
|----------------------|----------------------------------------------------------------------------------|
| <b>NAME</b>          | <b><i>sqrtf()</i></b> – compute a non-negative square root (ANSI)                |
| <b>SYNOPSIS</b>      | <pre>float sqrtf (     float x /* value to compute the square root of */ )</pre> |
| <b>DESCRIPTION</b>   | This routine returns the non-negative square root of $x$ in single precision.    |
| <b>INCLUDE FILES</b> | <b>math.h</b>                                                                    |
| <b>RETURNS</b>       | The single-precision square root of $x$ .                                        |
| <b>SEE ALSO</b>      | <b>mathALib</b>                                                                  |

---

## ***squeeze()***

|                    |                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <b><i>squeeze()</i></b> – reclaim fragmented free space on an RT-11 volume                    |
| <b>SYNOPSIS</b>    | <pre>STATUS squeeze (     char * devName /* RT-11 device to squeeze, e.g., "/fd0/" */ )</pre> |
| <b>DESCRIPTION</b> | This command moves data around on an RT-11 volume so that any areas of free space are merged. |

## ***sr()***

- NOTE** No device files should be open when this procedure is called. The subsequent condition of such files would be unknown and writing to them could corrupt the entire disk.
- RETURNS** OK, or ERROR if the device cannot be opened or squeezed.
- SEE ALSO** *usrLib*, *VxWorks Programmer's Guide: Target Shell*

---

## ***sr()***

- NAME** *sr()* – return the contents of the status register (MC680x0)
- SYNOPSIS**
- ```
int sr
(
    int taskId /* task ID, 0 means default task */
)
```
- DESCRIPTION** This command extracts the contents of the status register from the TCB of a specified task. If *taskId* is omitted or zero, the last task referenced is assumed.
- RETURNS** The contents of the status register.
- SEE ALSO** *dbgArchLib*, *VxWorks Programmer's Guide: Target Shell*

sramDevCreate()

- NAME** *sramDevCreate()* – create a PCMCIA memory disk device
- SYNOPSIS**
- ```
BLK_DEV *sramDevCreate
(
 int sock, /* socket no. */
 int bytesPerBlk, /* number of bytes per block */
 int blksPerTrack, /* number of blocks per track */
 int nBlocks, /* number of blocks on this device */
 int blkOffset /* no. of blks to skip at start of device */
)
```
- DESCRIPTION** This routine creates a PCMCIA memory disk device.

**RETURNS** A pointer to a block device structure (`BLK_DEV`), or `NULL` if memory cannot be allocated for the device structure.

**SEE ALSO** `sramDrv`, `ramDevCreate()`

---

## *sramDrv()*

**NAME** `sramDrv()` – install a PCMCIA SRAM memory driver

**SYNOPSIS**

```
STATUS sramDrv
(
 int sock /* socket no. */
)
```

**DESCRIPTION** This routine initializes a PCMCIA SRAM memory driver. It must be called once, before any other routines in the driver.

**RETURNS** `OK`, or `ERROR` if the I/O system cannot install the driver.

**SEE ALSO** `sramDrv`

---

## *sramMap()*

**NAME** `sramMap()` – map PCMCIA memory onto a specified ISA address space

**SYNOPSIS**

```
STATUS sramMap
(
 int sock, /* socket no. */
 int type, /* 0: common 1: attribute */
 int start, /* ISA start address */
 int stop, /* ISA stop address */
 int offset, /* card offset address */
 int extraws /* extra wait state */
)
```

**DESCRIPTION** This routine maps PCMCIA memory onto a specified ISA address space.

**RETURNS** `OK`, or `ERROR` if the memory cannot be mapped.

**SEE ALSO** `sramDrv`

***srand()***

---

***srand()***

|                      |                                                                                                                                                                                                                                                                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>srand()</i> – reset the value of the seed used to generate random numbers (ANSI)                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>      | <pre>void * srand (     uint_t seed /* random number seed */ )</pre>                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b>   | This routine resets the seed value used by <i>rand()</i> . If <i>srand()</i> is then called with the same seed value, the sequence of pseudo-random numbers is repeated. If <i>rand()</i> is called before any calls to <i>srand()</i> have been made, the same sequence shall be generated as when <i>srand()</i> is first called with the seed value of 1. |
| <b>INCLUDE FILES</b> | <i>stdlib.h</i>                                                                                                                                                                                                                                                                                                                                              |
| <b>RETURNS</b>       | N/A                                                                                                                                                                                                                                                                                                                                                          |

***sscanf()***

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>sscanf()</i> – read and convert characters from an ASCII string (ANSI)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <pre>int sscanf (     const char * str, /* string to scan */     const char * fmt /* format string */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>This routine reads characters from the string <i>str</i>, interprets them according to format specifications in the string <i>fmt</i>, which specifies the admissible input sequences and how they are to be converted for assignment, using subsequent arguments as pointers to the objects to receive the converted input.</p> <p>If there are insufficient arguments for the format, the behavior is undefined. If the format is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>The format is a multibyte character sequence, beginning and ending in its initial shift state. The format is composed of zero or more directives: one or more white-space</p> |

characters; an ordinary multibyte character (neither % nor a white-space character); or a conversion specification. Each conversion specification is introduced by the % character. After the %, the following appear in sequence:

- An optional assignment-suppressing character \*.
- An optional non-zero decimal integer that specifies the maximum field width.
- An optional **h** or **l** (**el**) indicating the size of the receiving object. The conversion specifiers **d**, **i**, and **n** should be preceded by **h** if the corresponding argument is a pointer to **short int** rather than a pointer to **int**, or by **l** if it is a pointer to **long int**. Similarly, the conversion specifiers **o**, **u**, and **x** shall be preceded by **h** if the corresponding argument is a pointer to **unsigned short int** rather than a pointer to **unsigned int**, or by **l** if it is a pointer to **unsigned long int**. Finally, the conversion specifiers **e**, **f**, and **g** shall be preceded by **l** if the corresponding argument is a pointer to **double** rather than a pointer to **float**. If an **h** or **l** appears with any other conversion specifier, the behavior is undefined.
- WARNING: ANSI C also specifies an optional **L** in some of the same contexts as **l** above, corresponding to a **long double \*** argument. However, the current release of the VxWorks libraries does not support **long double** data; using the optional **L** gives unpredictable results.
- A character that specifies the type of conversion to be applied. The valid conversion specifiers are described below.

The **sscanf()** routine executes each directive of the format in turn. If a directive fails, as detailed below, **sscanf()** returns. Failures are described as input failures (due to the unavailability of input characters), or matching failures (due to inappropriate input).

A directive composed of white-space character(s) is executed by reading input up to the first non-white-space character (which remains unread), or until no more characters can be read.

A directive that is an ordinary multibyte character is executed by reading the next characters of the stream. If one of the characters differs from one comprising the directive, the directive fails, and the differing and subsequent characters remain unread.

A directive that is a conversion specification defines a set of matching input sequences, as described below for each specifier. A conversion specification is executed in the following steps:

Input white-space characters (as specified by the **isspace()** function) are skipped, unless the specification includes a **l**, **c**, or **n** specifier.

An input item is read from the stream, unless the specification includes an **n** specifier. An input item is defined as the longest matching sequence of input characters, unless that exceeds a specified field width, in which case it is the initial subsequence of that length in the sequence. The first character, if any, after the input item remains unread. If the length of the input item is zero, the execution of the directive fails: this condition is a matching

**sscanf()**

failure, unless an error prevented input from the stream, in which case it is an input failure.

Except in the case of a % specifier, the input item is converted to a type appropriate to the conversion specifier. If the input item is not a matching sequence, the execution of the directive fails: this condition is a matching failure. Unless assignment suppression was indicated by a \*, the result of the conversion is placed in the object pointed to by the first argument following the *fmt* argument that has not already received a conversion result. If this object does not have an appropriate type, or if the result of the conversion cannot be represented in the space provided, the behavior is undefined.

The following conversion specifiers are valid:

**d**

Matches an optionally signed decimal integer whose format is the same as expected for the subject sequence of the *strtol()* function with the value 10 for the *base* argument. The corresponding argument should be a pointer to **int**.

**i**

Matches an optionally signed integer, whose format is the same as expected for the subject sequence of the *strtol()* function with the value 0 for the *base* argument. The corresponding argument should be a pointer to **int**.

**o**

Matches an optionally signed octal integer, whose format is the same as expected for the subject sequence of the *strtoul()* function with the value 8 for the *base* argument. The corresponding argument should be a pointer to **unsigned int**.

**u**

Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of the *strtoul()* function with the value 10 for the *base* argument. The corresponding argument should be a pointer to **unsigned int**.

**x**

Matches an optionally signed hexadecimal integer, whose format is the same as expected for the subject sequence of the *strtoul()* function with the value 16 for the *base* argument. The corresponding argument should be a pointer to **unsigned int**.

**e, f, g**

Match an optionally signed floating-point number, whose format is the same as expected for the subject string of the *strtod()* function. The corresponding argument should be a pointer to **float**.

**s**

Matches a sequence of non-white-space characters. The corresponding argument should be a pointer to the initial character of an array large enough to accept the sequence and a terminating null character, which will be added automatically.

**[**

Matches a non-empty sequence of characters from a set of expected characters (the

**scanset**). The corresponding argument should be a pointer to the initial character of an array large enough to accept the sequence and a terminating null character, which is added automatically. The conversion specifier includes all subsequent character in the format string, up to and including the matching right bracket (]). The characters between the brackets (the **scanlist**) comprise the scanset, unless the character after the left bracket is a circumflex (^) in which case the scanset contains all characters that do not appear in the scanlist between the circumflex and the right bracket. If the conversion specifier begins with "[]" or "[^]", the right bracket character is in the scanlist and the next right bracket character is the matching right bracket that ends the specification; otherwise the first right bracket character is the one that ends the specification.

**c**

Matches a sequence of characters of the number specified by the field width (1 if no field width is present in the directive). The corresponding argument should be a pointer to the initial character of an array large enough to accept the sequence. No null character is added.

**P**

Matches an implementation-defined set of sequences, which should be the same as the set of sequences that may be produced by the %p conversion of the *fprintf()* function. The corresponding argument should be a pointer to a pointer to **void**. VxWorks defines its pointer input field to be consistent with pointers written by the *fprintf()* function ("0x" hexadecimal notation). If the input item is a value converted earlier during the same program execution, the pointer that results should compare equal to that value; otherwise the behavior of the %p conversion is undefined.

**n**

No input is consumed. The corresponding argument should be a pointer to **int** into which the number of characters read from the input stream so far by this call to *sscanf()* is written. Execution of a %n directive does not increment the assignment count returned when *sscanf()* completes execution.

**%**

Matches a single %; no conversion or assignment occurs. The complete conversion specification is %%.

If a conversion specification is invalid, the behavior is undefined.

The conversion specifiers **E**, **G**, and **X** are also valid and behave the same as **e**, **g**, and **x**, respectively.

If end-of-file is encountered during input, conversion is terminated. If end-of-file occurs before any characters matching the current directive have been read (other than leading white space, where permitted), execution of the current directive terminates with an input failure; otherwise, unless execution of the current directive is terminated with a matching failure, execution of the following directive (if any) is terminated with an input failure.

If conversion terminates on a conflicting input character, the offending input character is left unread in the input stream. Trailing white space (including new-line characters) is left unread unless matched by a directive. The success of literal matches and suppressed assignments is not directly determinable other than via the %n directive.

**INCLUDE FILES**    **fiolib.h**

**RETURNS**        The number of input items assigned, which can be fewer than provided for, or even zero, in the event of an early matching failure; or EOF if an input failure occurs before any conversion.

**SEE ALSO**        **fiolib**, **fscanf()**, **scanf()**, *American National Standard for Information Systems – Programming Language – C, ANSI X3.159-1989: Input/Output (stdio.h)*

## **st16552DevInit()**

**NAME**            **st16552DevInit()** – initialise an ST16552 channel

**SYNOPSIS**

```
void st16552DevInit
(
 ST16552_CHAN * pChan
)
```

**DESCRIPTION**    This routine initialises some SIO\_CHAN function pointers and then resets the chip in a quiescent state. Before this routine is called, the BSP must already have initialised all the device addresses, etc. in the ST16552\_CHAN structure.

**RETURNS**        N/A

**SEE ALSO**        **st16552Sio**

---

## **st16552Int()**

**NAME**            **st16552Int()** – interrupt level processing

**SYNOPSIS**

```
void st16552Int
(
 ST16552_CHAN * pChan /* ptr to struct describing channel */
)
```

**DESCRIPTION** This routine handles interrupts from the UART.

**RETURNS** N/A

**SEE ALSO** *st16552Sio*

---

## *st16552IntEx()*

**NAME** *st16552IntEx()* – miscellaneous interrupt processing

**SYNOPSIS**

```
void st16552IntEx
(
 ST16552_CHAN * pChan /* ptr to struct describing channel */
)
```

**DESCRIPTION** This routine handles miscellaneous interrupts on the UART.

**RETURNS** N/A

**SEE ALSO** *st16552Sio*

---

## *st16552IntRd()*

**NAME** *st16552IntRd()* – handle a receiver interrupt

**SYNOPSIS**

```
void st16552IntRd
(
 ST16552_CHAN * pChan /* ptr to struct describing channel */
)
```

**DESCRIPTION** This routine handles read interrupts from the UART.

**RETURNS** N/A

**SEE ALSO** *st16552Sio*

## ***st16552IntWr()***

**NAME** *st16552IntWr()* – handle a transmitter interrupt

**SYNOPSIS**

```
void st16552IntWr
(
 ST16552_CHAN * pChan /* ptr to struct describing channel */
)
```

**DESCRIPTION** This routine handles write interrupts from the UART.

**RETURNS** N/A

**SEE ALSO** *st16552Sio*

---

## ***st16552MuxInt()***

**NAME** *st16552MuxInt()* – multiplexed interrupt level processing

**SYNOPSIS**

```
void st16552MuxInt
(
 ST16552_MUX * pMux /* ptr to struct describing multiplexed chans */
)
```

**DESCRIPTION** This routine handles multiplexed interrupts from the DUART. It assumes that channels 0 and 1 are connected so that they produce the same interrupt.

**RETURNS** N/A

**SEE ALSO** *st16552Sio*

---

## *statfs()*

|                    |                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>statfs()</i> – get file status information using a pathname (POSIX)                                                                                                                                           |
| <b>SYNOPSIS</b>    | <pre>STATUS statfs (     char *          name, /* name of file to check */     struct statfs * pStat /* pointer to statfs structure */ )</pre>                                                                   |
| <b>DESCRIPTION</b> | <p>This routine obtains various characteristics of a file system. This routine is equivalent to <i>fstatfs()</i>, except that the <i>name</i> of the file is specified, rather than an open file descriptor.</p> |

***stdioFp()***

The *pStat* parameter is a pointer to a **statfs** structure (defined in **stat.h**). This structure must have already been allocated before this routine is called.

Upon return, the fields in the **statfs** structure are updated to reflect the characteristics of the file.

**RETURNS** OK or ERROR.

**SEE ALSO** *dirLib*, *fstatfs()*, *ls()*

***stdioFp()***

**NAME** *stdioFp()* – return the standard input/output/error FILE of the current task

**SYNOPSIS**

```
FILE * stdioFp
(
 int stdFd /* fd of standard FILE to return (0,1,2) */
)
```

**DESCRIPTION** This routine returns the specified standard FILE structure address of the current task. It is provided primarily to give access to standard input, standard output, and standard error from the shell, where the usual **stdin**, **stdout**, **stderr** macros cannot be used.

**INCLUDE FILES** *stdio.h*

**RETURNS** The standard FILE structure address of the specified file descriptor, for the current task.

**SEE ALSO** *ansiStdio*

***stdioInit()***

**NAME** *stdioInit()* – initialize standard I/O support

**SYNOPSIS** `STATUS stdioInit (void)`

**DESCRIPTION** This routine installs standard I/O support. It must be called before using **stdio** buffering. If **INCLUDE\_STDIO** is defined in **configAll.h**, it is called automatically by the root task *usrRoot()* in *usrConfig.c*.

**RETURNS** OK, or ERROR if the standard I/O facilities cannot be installed.

**SEE ALSO** ansiStdio

---

## *stdioShow()*

**NAME** *stdioShow()* – display file pointer internals

**SYNOPSIS**

```
STATUS stdioShow
(
 FILE * fp, /* stream */
 int level /* level */
)
```

**DESCRIPTION** This routine displays information about a specified stream.

**RETURNS** OK, or ERROR if the file pointer is invalid.

**SEE ALSO** ansiStdio

---

## *stdioShowInit()*

**NAME** *stdioShowInit()* – initialize the standard I/O show facility

**SYNOPSIS** STATUS stdioShowInit (void)

**DESCRIPTION** This routine links the file pointer show routine into the VxWorks system. It is called automatically when this show facility is configured into VxWorks using either of the following methods:

- If you use the configuration header files, define **INCLUDE\_SHOW\_ROUTINES** in **config.h**.
- If you use the Tornado project facility, select **INCLUDE\_STDIO\_SHOW**.

**RETURNS** OK, or ERROR if an error occurs installing the file pointer show routine.

**SEE ALSO** ansiStdio

**strcat()**

---

**strcat()**

|                      |                                                                                                                                                            |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>strcat()</i> – concatenate one string to another (ANSI)                                                                                                 |
| <b>SYNOPSIS</b>      | <pre>char * strcat (     char *      destination, /* string to be appended to */     const char * append     /* string to append to destination */ )</pre> |
| <b>DESCRIPTION</b>   | This routine appends a copy of string <i>append</i> to the end of string <i>destination</i> . The resulting string is null-terminated.                     |
| <b>INCLUDE FILES</b> | <code>string.h</code>                                                                                                                                      |
| <b>RETURNS</b>       | A pointer to <i>destination</i> .                                                                                                                          |
| <b>SEE ALSO</b>      | <code>ansiString</code>                                                                                                                                    |

---

**strchr()**

|                      |                                                                                                                                                 |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>strchr()</i> – find the first occurrence of a character in a string (ANSI)                                                                   |
| <b>SYNOPSIS</b>      | <pre>char * strchr (     const char * s, /* string in which to search */     int        c   /* character to find in string */ )</pre>           |
| <b>DESCRIPTION</b>   | This routine finds the first occurrence of character <i>c</i> in string <i>s</i> . The terminating null is considered to be part of the string. |
| <b>INCLUDE FILES</b> | <code>string.h</code>                                                                                                                           |
| <b>RETURNS</b>       | The address of the located character, or NULL if the character is not found.                                                                    |
| <b>SEE ALSO</b>      | <code>ansiString</code>                                                                                                                         |

---

## *strcmp()*

|                      |                                                                                                                                                                       |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>strcmp()</i> – compare two strings lexicographically (ANSI)                                                                                                        |
| <b>SYNOPSIS</b>      | <pre>int strcmp (     const char * s1, /* string to compare */     const char * s2 /* string to compare s1 to */ )</pre>                                              |
| <b>DESCRIPTION</b>   | This routine compares string <i>s1</i> to string <i>s2</i> lexicographically.                                                                                         |
| <b>INCLUDE FILES</b> | <b>string.h</b>                                                                                                                                                       |
| <b>RETURNS</b>       | An integer greater than, equal to, or less than 0, according to whether <i>s1</i> is lexicographically greater than, equal to, or less than <i>s2</i> , respectively. |
| <b>SEE ALSO</b>      | <b>ansiString</b>                                                                                                                                                     |

---

## *strcoll()*

|                      |                                                                                                                                                                                                                      |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>strcoll()</i> – compare two strings as appropriate to LC_COLLATE (ANSI)                                                                                                                                           |
| <b>SYNOPSIS</b>      | <pre>int strcoll (     const char * s1, /* string 1 */     const char * s2 /* string 2 */ )</pre>                                                                                                                    |
| <b>DESCRIPTION</b>   | This routine compares two strings, both interpreted as appropriate to the LC_COLLATE category of the current locale.                                                                                                 |
| <b>INCLUDE FILES</b> | <b>string.h</b>                                                                                                                                                                                                      |
| <b>RETURNS</b>       | An integer greater than, equal to, or less than zero, according to whether string <i>s1</i> is greater than, equal to, or less than string <i>s2</i> when both are interpreted as appropriate to the current locale. |
| <b>SEE ALSO</b>      | <b>ansiString</b>                                                                                                                                                                                                    |

## **strcpy()**

|                      |                                                                                                                        |
|----------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>strcpy()</i> – copy one string to another (ANSI)                                                                    |
| <b>SYNOPSIS</b>      | <pre>char * strcpy (     char *      s1, /* string to copy to */     const char * s2 /* string to copy from */ )</pre> |
| <b>DESCRIPTION</b>   | This routine copies string <i>s2</i> (including EOS) to string <i>s1</i> .                                             |
| <b>INCLUDE FILES</b> | <b>string.h</b>                                                                                                        |
| <b>RETURNS</b>       | A pointer to <i>s1</i> .                                                                                               |
| <b>SEE ALSO</b>      | <b>ansiString</b>                                                                                                      |

---

## **strcspn()**

|                      |                                                                                                                                                             |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>strcspn()</i> – return the string length up to the first character from a given set (ANSI)                                                               |
| <b>SYNOPSIS</b>      | <pre>size_t strcspn (     const char * s1, /* string to search */     const char * s2 /* set of characters to look for in s1 */ )</pre>                     |
| <b>DESCRIPTION</b>   | This routine computes the length of the maximum initial segment of string <i>s1</i> that consists entirely of characters not included in string <i>s2</i> . |
| <b>INCLUDE FILES</b> | <b>string.h</b>                                                                                                                                             |
| <b>RETURNS</b>       | The length of the string segment.                                                                                                                           |
| <b>SEE ALSO</b>      | <b>ansiString, strpbrk(), strspn()</b>                                                                                                                      |

**strftime( )**

---

**strftime( )**

**NAME** `strftime( )` – convert broken-down time into a formatted string (ANSI)

**SYNOPSIS**

```
size_t strftime
(
 char * s, /* string array */
 size_t n, /* maximum size of array */
 const char * format, /* format of output string */
 const struct tm * tptr /* broken-down time */
)
```

**DESCRIPTION** This routine formats the broken-down time in *tptr* based on the conversion specified in the string *format*, and places the result in the string *s*.

The format is a multibyte character sequence, beginning and ending in its initial state. The *format* string consists of zero or more conversion specifiers and ordinary multibyte characters. A conversion specifier consists of a % character followed by a character that determines the behavior of the conversion. All ordinary multibyte characters (including the terminating NULL character) are copied unchanged to the array. If copying takes place between objects that overlap, the behavior is undefined. No more than *n* characters are placed into the array.

Each conversion specifier is replaced by appropriate characters as described in the following list. The appropriate characters are determined by the LC\_TIME category of the current locale and by the values contained in the structure pointed to by *tptr*.

- %a the locale's abbreviated weekday name.
- %A the locale's full weekday name.
- %b the locale's abbreviated month name.
- %B the locale's full month name.
- %c the locale's appropriate date and time representation.
- %d the day of the month as decimal number (01-31).
- %H the hour (24-hour clock) as a decimal number (00-23).
- %I the hour (12-hour clock) as a decimal number (01-12).
- %j the day of the year as decimal number (001-366).
- %m the month as a decimal number (01-12).
- %M the minute as a decimal number (00-59).
- %P the locale's equivalent of the AM/PM designations associated with a 12-hour clock.

|                 |                                                                                                        |
|-----------------|--------------------------------------------------------------------------------------------------------|
| <code>%S</code> | the second as a decimal number (00-59).                                                                |
| <code>%U</code> | the week number of the year (first Sunday as the first day of week 1) as a decimal number (00-53).     |
| <code>%w</code> | the weekday as a decimal number (0-6), where Sunday is 0.                                              |
| <code>%W</code> | the week number of the year (the first Monday as the first day of week 1) as a decimal number (00-53). |
| <code>%x</code> | the locale's appropriate date representation.                                                          |
| <code>%X</code> | the locale's appropriate time representation.                                                          |
| <code>%y</code> | the year without century as a decimal number (00-99).                                                  |
| <code>%Y</code> | the year with century as a decimal number.                                                             |
| <code>%Z</code> | the time zone name or abbreviation, or by no characters if no time zone is determinable.               |
| <code>%%</code> | <code>%</code> .                                                                                       |

**INCLUDE FILES**     `time.h`

**RETURNS**            The number of characters in *s*, not including the terminating null character -- or zero if the number of characters in *s*, including the null character, is more than *n* (in which case the contents of *s* are indeterminate).

**SEE ALSO**            `ansiTime`

---

## ***strlen()***

**NAME**                `strlen()` – determine the length of a string (ANSI)

**SYNOPSIS**            `size_t strlen`  
                      (  
                      `const char * s /* string */`  
                      )

**DESCRIPTION**        This routine returns the number of characters in *s*, not including EOS.

**INCLUDE FILES**       `string.h`

**RETURNS**            The number of non-null characters in the string.

**SEE ALSO**            `ansiString`

**strncat()**

---

**strncat()**

|                      |                                                                                                                                                                                      |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>strncat()</i> – concatenate characters from one string to another (ANSI)                                                                                                          |
| <b>SYNOPSIS</b>      | <pre>char * strncat (     char *      dst, /* string to append to */     const char * src, /* string to append */     size_t      n    /* max no. of characters to append */ )</pre> |
| <b>DESCRIPTION</b>   | This routine appends up to <i>n</i> characters from string <i>src</i> to the end of string <i>dst</i> .                                                                              |
| <b>INCLUDE FILES</b> | string.h                                                                                                                                                                             |
| <b>RETURNS</b>       | A pointer to the null-terminated string <i>s1</i> .                                                                                                                                  |
| <b>SEE ALSO</b>      | ansiString                                                                                                                                                                           |

|                      |                                                                                                                                                                                        |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>strncmp()</i> – compare the first <i>n</i> characters of two strings (ANSI)                                                                                                         |
| <b>SYNOPSIS</b>      | <pre>int strncmp (     const char * s1, /* string to compare */     const char * s2, /* string to compare s1 to */     size_t      n    /* max no. of characters to compare */ )</pre> |
| <b>DESCRIPTION</b>   | This routine compares up to <i>n</i> characters of string <i>s1</i> to string <i>s2</i> lexicographically.                                                                             |
| <b>INCLUDE FILES</b> | string.h                                                                                                                                                                               |
| <b>RETURNS</b>       | An integer greater than, equal to, or less than 0, according to whether <i>s1</i> is lexicographically greater than, equal to, or less than <i>s2</i> , respectively.                  |
| <b>SEE ALSO</b>      | ansiString                                                                                                                                                                             |

## *strpbrk()*

|                      |                                                                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>strpbrk()</i> – find the first occurrence in a string of a character from a given set (ANSI)                                         |
| <b>SYNOPSIS</b>      | <pre>char * strpbrk (     const char * s1, /* string to search */     const char * s2 /* set of characters to look for in s1 */ )</pre> |
| <b>DESCRIPTION</b>   | This routine locates the first occurrence in string <i>s1</i> of any character from string <i>s2</i> .                                  |
| <b>INCLUDE FILES</b> | <i>string.h</i>                                                                                                                         |
| <b>RETURNS</b>       | A pointer to the character found in <i>s1</i> , or NULL if no character from <i>s2</i> occurs in <i>s1</i> .                            |
| <b>SEE ALSO</b>      | <i>ansiString</i> , <i>strcspn()</i>                                                                                                    |

## ***strrchr()***

**NAME** *strrchr()* – find the last occurrence of a character in a string (ANSI)

**SYNOPSIS**

```
char * strrchr
(
 const char * s, /* string to search */
 int c /* character to look for */
)
```

**DESCRIPTION** This routine locates the last occurrence of *c* in the string pointed to by *s*. The terminating null is considered to be part of the string.

**INCLUDE FILES** *string.h*

**RETURNS** A pointer to the last occurrence of the character, or NULL if the character is not found.

**SEE ALSO** *ansiString*

---

## ***strspn()***

**NAME** *strspn()* – return the string length up to the first character not in a given set (ANSI)

**SYNOPSIS**

```
size_t strspn
(
 const char * s, /* string to search */
 const char * sep /* set of characters to look for in s */
)
```

**DESCRIPTION** This routine computes the length of the maximum initial segment of string *s* that consists entirely of characters from the string *sep*.

**INCLUDE FILES** *string.h*

**RETURNS** The length of the string segment.

**SEE ALSO** *ansiString, strcspn()*

---

## ***strstr()***

| <b>NAME</b>        | <i>strtod()</i> – convert the initial portion of a string to a double (ANSI)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <pre>double strtod (     const char * s, /* string to convert */     char * * endptr /* ptr to final string */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>This routine converts the initial portion of a specified string <i>s</i> to a double. First, it decomposes the input string into three parts: an initial, possibly empty, sequence of white-space characters (as specified by the <i>isspace()</i> function); a subject sequence resembling a floating-point constant; and a final string of one or more unrecognized characters, including the terminating null character of the input string. Then, it attempts to convert the subject sequence to a floating-point number, and returns the result.</p> <p>The expected form of the subject sequence is an optional plus or minus decimal-point character, then an optional exponent part but no floating suffix. The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character, that is of the expected form. The subject sequence contains no</p> |

***strtok()***

characters if the input string is empty or consists entirely of white space, or if the first non-white-space character is other than a sign, a digit, or a decimal-point character.

If the subject sequence has the expected form, the sequence of characters starting with the first digit or the decimal-point character (whichever occurs first) is interpreted as a floating constant, except that the decimal-point character is used in place of a period, and that if neither an exponent part nor a decimal-point character appears, a decimal point is assumed to follow the last digit in the string. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final string is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

In other than the "C" locale, additional implementation-defined subject sequence forms may be accepted. VxWorks supports only the "C" locale.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *s* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

**INCLUDE FILES**     **stdlib.h**

**RETURNS**           The converted value, if any. If no conversion could be performed, it returns zero. If the correct value is outside the range of representable values, it returns plus or minus **HUGE\_VAL** (according to the sign of the value), and stores the value of the macro **ERANGE** in **errno**. If the correct value would cause underflow, it returns zero and stores the value of the macro **ERANGE** in **errno**.

## ***strtok()***

**NAME**               ***strtok()*** – break down a string into tokens (ANSI)

**SYNOPSIS**

```
char * strtok
(
 char * string, /* string */
 const char * separator /* separator indicator */
)
```

**DESCRIPTION**      A sequence of calls to this routine breaks the string *string* into a sequence of tokens, each of which is delimited by a character from the string *separator*. The first call in the sequence has *string* as its first argument, and is followed by calls with a null pointer as their first argument. The separator string may be different from call to call.

The first call in the sequence searches *string* for the first character that is not contained in the current separator string. If the character is not found, there are no tokens in *string* and *strtok()* returns a null pointer. If the character is found, it is the start of the first token.

*strtok()* then searches from there for a character that is contained in the current separator string. If the character is not found, the current token expands to the end of the string pointed to by *string*, and subsequent searches for a token will return a null pointer. If the character is found, it is overwritten by a null character, which terminates the current token. *strtok()* saves a pointer to the following character, from which the next search for a token will start. (Note that because the separator character is overwritten by a null character, the input string is modified as a result of this call.)

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

The implementation behaves as if *strtok()* is called by no library functions.

| SYNOPSIS    | <pre>char * strtok_r (     char *      string,      /* string to break into tokens */     const char * separators, /* the separators */     char * *    ppLast       /* pointer to serve as string index */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DESCRIPTION | <p>This routine considers the null-terminated string <i>string</i> as a sequence of zero or more text tokens separated by spans of one or more characters from the separator string <i>separators</i>. The argument <i>ppLast</i> points to a user-provided pointer which in turn points to the position within <i>string</i> at which scanning should begin.</p> <p>In the first call to this routine, <i>string</i> points to a null-terminated string; <i>separators</i> points to a null-terminated string of separator characters; and <i>ppLast</i> points to a NULL pointer. The function returns a pointer to the first character of the first token, writes a null character</p> |

**strtol()**

into *string* immediately following the returned token, and updates the pointer to which *ppLast* points so that it points to the first character following the null written into *string*. (Note that because the separator character is overwritten by a null character, the input string is modified as a result of this call.)

In subsequent calls *string* must be a NULL pointer and *ppLast* must be unchanged so that subsequent calls will move through the string *string*, returning successive tokens until no tokens remain. The separator string *separators* may be different from call to call. When no token remains in *string*, a NULL pointer is returned.

**INCLUDE FILES**     **string.h**

**RETURNS**            A pointer to the first character of a token, or a NULL pointer if there is no token.

**SEE ALSO**            **ansiString, strtok()**

**strtol()**

**NAME**                **strtol()** – convert a string to a long integer (ANSI)

**SYNOPSIS**

```
long strtol
(
 const char * nptr, /* string to convert */
 char * * endptr, /* ptr to final string */
 int base /* radix */
)
```

**DESCRIPTION**      This routine converts the initial portion of a string *nptr* to **long int** representation. First, it decomposes the input string into three parts: an initial, possibly empty, sequence of white-space characters (as specified by *isspace()*); a subject sequence resembling an integer represented in some radix determined by the value of *base*; and a final string of one or more unrecognized characters, including the terminating NULL character of the input string. Then, it attempts to convert the subject sequence to an integer number, and returns the result.

If the value of *base* is zero, the expected form of the subject sequence is that of an integer constant, optionally preceded by a plus or minus sign, but not including an integer suffix. If the value of *base* is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by *base* optionally preceded by a plus or minus sign, but not including an integer suffix. The letters from a (or A) through to z (or Z) are ascribed the values 10 to 35; only letters whose ascribed values are less than *base* are premitted. If the value of *base* is 16, the characters 0x

or 0X may optionally precede the sequence of letters and digits, following the sign if present.

The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character, that is of the expected form. The subject sequence contains no characters if the input string is empty or consists entirely of white space, or if the first non-white-space character is other than a sign or a permissible letter or digit.

If the subject sequence has the expected form and the value of *base* is zero, the sequence of characters starting with the first digit is interpreted as an integer constant. If the subject sequence has the expected form and the value of *base* is between 2 and 36, it is used as the *base* for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final string is stored in the object pointed to by *endptr*, provided that *endptr* is not a NULL pointer.

In other than the "C" locale, additional implementation-defined subject sequence forms may be accepted. VxWorks supports only the "C" locale; it assumes that the upper- and lower-case alphabets and digits are each contiguous.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *nptr* is stored in the object pointed to by *endptr*, provided that *endptr* is not a NULL pointer.

**INCLUDE FILES**     **stdlib.h**

**RETURNS**           The converted value, if any. If no conversion could be performed, it returns zero. If the correct value is outside the range of representable values, it returns **LONG\_MAX** or **LONG\_MIN** (according to the sign of the value), and stores the value of the macro **ERANGE** in **errno**.

## **strtoul()**

**NAME**               **strtoul()** – convert a string to an unsigned long integer (ANSI)

**SYNOPSIS**           **ulong\_t strtoul**  
                  (  
                  **const char \* nptr,**    /\* string to convert \*/  
                  **char \* \*        endptr,** /\* ptr to final string \*/  
                  **int             base    /\* radix \*/**  
                  )

**strtoul()****DESCRIPTION**

This routine converts the initial portion of a string *nptr* to **unsigned long int** representation. First, it decomposes the input string into three parts: an initial, possibly empty, sequence of white-space characters (as specified by *isspace()*); a subject sequence resembling an unsigned integer represented in some radix determined by the value *base*; and a final string of one or more unrecognized characters, including the terminating null character of the input string. Then, it attempts to convert the subject sequence to an unsigned integer, and returns the result.

If the value of *base* is zero, the expected form of the subject sequence is that of an integer constant, optionally preceded by a plus or minus sign, but not including an integer suffix. If the value of *base* is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by letters from a (or A) through z (or Z) which are ascribed the values 10 to 35; only letters whose ascribed values are less than *base* are premitted. If the value of *base* is 16, the characters 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.

The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character, that is of the expected form. The subject sequence contains no characters if the input string is empty or consists entirely of white space, or if the first non-white-space character is other than a sign or a permissible letter or digit.

If the subject sequence has the expected form and the value of *base* is zero, the sequence of characters starting with the first digit is interpreted as an integer constant. If the subject sequence has the expected form and the value of *base* is between 2 and 36, it is used as the *base* for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final string is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

In other than the "C" locale, additional implementation-defined subject sequence forms may be accepted. VxWorks supports only the "C" locale; it assumes that the upper- and lower-case alphabets and digits are each contiguous.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *nptr* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

**INCLUDE FILES****stdlib.h****RETURNS**

The converted value, if any. If no conversion could be performed it returns zero. If the correct value is outside the range of representable values, it returns **ULONG\_MAX**, and stores the value of the macro **ERANGE** in *errno*.

| <b>NAME</b>          | <i>strxfrm()</i> – transform up to <i>n</i> characters of <i>s2</i> into <i>s1</i> (ANSI)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>      | <pre>size_t strxfrm (     char *      s1, /* string out */     const char * s2, /* string in */     size_t     n /* size of buffer */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b>   | This routine transforms string <i>s2</i> and places the resulting string in <i>s1</i> . The transformation is such that if <i>strcmp()</i> is applied to two transformed strings, it returns a value greater than, equal to, or less than zero, corresponding to the result of the <i>strcoll()</i> function applied to the same two original strings. No more than <i>n</i> characters are placed into the resulting <i>s1</i> , including the terminating null character. If <i>n</i> is zero, <i>s1</i> is permitted to be a NULL pointer. If copying takes place between objects that overlap, the behavior is undefined. |
| <b>INCLUDE FILES</b> | <i>string.h</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>RETURNS</b>       | The length of the transformed string, not including the terminating null character. If the value is <i>n</i> or more, the contents of <i>s1</i> are indeterminate.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SEE ALSO</b>      | <i>ansiString</i> , <i>strcmp()</i> , <i>strcoll()</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## *swab()*

|                    |                                                                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>swab()</i> – swap bytes                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <pre>void swab (     char * source,      /* pointer to source buffer */     char * destination, /* pointer to destination buffer */     int  nbytes        /* number of bytes to exchange */ )</pre>                       |
| <b>DESCRIPTION</b> | This routine gets the specified number of bytes from <i>source</i> , exchanges the adjacent even and odd bytes, and puts them in <i>destination</i> . The buffers <i>source</i> and <i>destination</i> should not overlap. |

**symAdd()**

|                 |                                                                                                                                                                                             |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NOTE</b>     | On some CPUs, <i>swab()</i> will cause an exception if the buffers are unaligned. In such cases, use <i>uswab()</i> for unaligned swaps.<br><br>It is an error for <i>nbytes</i> to be odd. |
| <b>RETURNS</b>  | N/A                                                                                                                                                                                         |
| <b>SEE ALSO</b> | <b>bLib</b> , <i>uswab()</i>                                                                                                                                                                |

---

**symAdd()**

|                    |                                                                                                                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>symAdd()</i> – create and add a symbol to a symbol table, including a group number                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <pre> STATUS symAdd (     SYMTAB_ID symTblId, /* symbol table to add symbol to */     char *    name,     /* pointer to symbol name string */     char *    value,    /* symbol address */     SYM_TYPE  type,     /* symbol type */     UINT16    group    /* symbol group */ ) </pre>                                     |
| <b>DESCRIPTION</b> | This routine allocates a symbol <i>name</i> and adds it to a specified symbol table <i>symTblId</i> with the specified parameters <i>value</i> , <i>type</i> , and <i>group</i> . The <i>group</i> parameter specifies the group number assigned to a module when it is loaded; see the manual entry for <b>moduleLib</b> . |
| <b>RETURNS</b>     | OK, or ERROR if the symbol table is invalid or there is insufficient memory for the symbol to be allocated.                                                                                                                                                                                                                 |
| <b>SEE ALSO</b>    | <b>symLib</b> , <b>moduleLib</b>                                                                                                                                                                                                                                                                                            |

---

**symEach()**

|                 |                                                                                                                                                   |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>     | <i>symEach()</i> – call a routine to examine each entry in a symbol table                                                                         |
| <b>SYNOPSIS</b> | <pre> SYMBOL *symEach (     SYMTAB_ID symTblId, /* pointer to symbol table */     FUNCPTR   routine, /* func to call for each tbl entry */ </pre> |

```
int routineArg /* arbitrary user-supplied arg */
)
```

**DESCRIPTION** This routine calls a user-supplied routine to examine each entry in the symbol table; it calls the specified routine once for each entry. The routine should be declared as follows:

```
BOOL routine
(
char *name, /* entry name */
int val, /* value associated with entry */
SYM_TYPE type, /* entry type */
int arg, /* arbitrary user-supplied arg */
UINT16 group /* group number */
)
```

The user-supplied routine should return TRUE if *symEach()* is to continue calling it for each entry, or FALSE if it is done and *symEach()* can exit.

**RETURNS** A pointer to the last symbol reached, or NULL if all symbols are reached.

**SEE ALSO** *symLib*

## *symFindByName()*

**NAME** *symFindByName()* – look up a symbol by name

**SYNOPSIS**

```
STATUS symFindByName
(
SYM_TAB_ID symTblId, /* ID of symbol table to look in */
char * name, /* symbol name to look for */
char * *pValue, /* where to put symbol value */
SYM_TYPE * pType /* where to put symbol type */
)
```

**DESCRIPTION** This routine searches a symbol table for a symbol matching a specified name. If the symbol is found, its value and type are copied to *pValue* and *pType*. If multiple symbols have the same name but differ in type, the routine chooses the matching symbol most recently added to the symbol table.

To search the global VxWorks symbol table, specify *sysSymTbl* as *symTblId*.

**RETURNS** OK, or ERROR if the symbol table ID is invalid or the symbol cannot be found.

**SEE ALSO** *symLib*

---

## **symFindByNameAndType()**

**NAME** *symFindByNameAndType()* – look up a symbol by name and type

**SYNOPSIS**

```
STATUS symFindByNameAndType
(
 SYMTAB_ID symTblId, /* ID of symbol table to look in */
 char * name, /* symbol name to look for */
 char * *pValue, /* where to put symbol value */
 SYM_TYPE * pType, /* where to put symbol type */
 SYM_TYPE sType, /* symbol type to look for */
 SYM_TYPE mask /* bits in sType to pay attention to */
)
```

**DESCRIPTION** This routine searches a symbol table for a symbol matching both name and type (*name* and *sType*). If the symbol is found, its value and type are copied to *pValue* and *pType*. The *mask* parameter can be used to match sub-classes of type.

To search the global VxWorks symbol table, specify **sysSymTbl** as *symTblId*.

**RETURNS** OK, or ERROR if the symbol table ID is invalid or the symbol is not found.

**SEE ALSO** *symLib*

---

## **symFindByValue()**

**NAME** *symFindByValue()* – look up a symbol by value

**SYNOPSIS**

```
STATUS symFindByValue
(
 SYMTAB_ID symTblId, /* ID of symbol table to look in */
 UINT value, /* value of symbol to find */
 char * name, /* where to put symbol name string */
 int * pValue, /* where to put symbol value */
 SYM_TYPE * pType /* where to put symbol type */
)
```

**DESCRIPTION** This routine searches a symbol table for a symbol matching a specified value. If there is no matching entry, it chooses the table entry with the next lower value. The symbol name (with terminating EOS), the actual value, and the type are copied to *name*, *pValue*, and *pType*.

For the *name* buffer, allocate `MAX_SYS_SYM_LEN + 1` bytes. The value `MAX_SYS_SYM_LEN` is defined in `sysSymTbl.h`.

To search the global VxWorks symbol table, specify `sysSymTbl` as *symTblId*.

**RETURNS** OK, or ERROR if *value* is less than the lowest value in the table.

**SEE ALSO** `symLib`

## *symFindByValueAndType( )*

**NAME** *symFindByValueAndType( )* – look up a symbol by value and type

**SYNOPSIS**

```
STATUS symFindByValueAndType
(
 SYMTAB_ID symTblId, /* ID of symbol table to look in */
 UINT value, /* value of symbol to find */
 char * name, /* where to put symbol name string */
 int * pValue, /* where to put symbol value */
 SYM_TYPE * pType, /* where to put symbol type */
 SYM_TYPE sType, /* symbol type to look for */
 SYM_TYPE mask /* bits in sType to pay attention to */
)
```

**DESCRIPTION** This routine searches a symbol table for a symbol matching both value and type (*value* and *sType*). If there is no matching entry, it chooses the table entry with the next lower value. The symbol name (with terminating EOS), the actual value, and the type are copied to *name*, *pValue*, and *pType*. The *mask* parameter can be used to match sub-classes of type.

For the *name* buffer, allocate `MAX_SYS_SYM_LEN + 1` bytes. The value `MAX_SYS_SYM_LEN` is defined in `sysSymTbl.h`.

To search the global VxWorks symbol table, specify `sysSymTbl` as *symTblId*.

**RETURNS** OK, or ERROR if *value* is less than the lowest value in the table.

|                    |                                                                                                                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>symSyncLibInit()</i> – initialize host/target symbol table synchronization                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <pre>void symSyncLibInit ( )</pre>                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | This routine initializes host/target symbol table synchronization. To enable synchronization, it must be called before a target server is started. It is called automatically if the configuration macro <code>INCLUDE_SYM_TBL_SYNC</code> is defined. |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                    |
| <b>SEE ALSO</b>    | <code>symSyncLib</code>                                                                                                                                                                                                                                |

## *symSyncTimeoutSet()*

|                    |                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>symSyncTimeoutSet()</i> – set WTX timeout                                                             |
| <b>SYNOPSIS</b>    | <pre>UINT32 symSyncTimeoutSet<br/>(<br/>    UINT32 timeout /* WTX timeout in milliseconds */<br/>)</pre> |
| <b>DESCRIPTION</b> | This routine sets the WTX timeout between target server and synchronization task.                        |
| <b>RETURNS</b>     | If <i>timeout</i> is 0, the current timeout, otherwise the new timeout value in milliseconds.            |
| <b>SEE ALSO</b>    | <code>symSyncLib</code>                                                                                  |

---

## *symTblCreate()*

|                 |                                                                                                                                                                                           |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>     | <i>symTblCreate()</i> – create a symbol table                                                                                                                                             |
| <b>SYNOPSIS</b> | <pre>SYMTAB_ID symTblCreate<br/>(<br/>    int     hashSizeLog2, /* size of hash table as a power of 2 */<br/>    BOOL    sameNameOk,  /* allow 2 symbols of same name &amp; type */</pre> |

```
 PART_ID symPartId /* memory part ID for symbol allocation */
)
```

**DESCRIPTION** This routine creates and initializes a symbol table with a hash table of a specified size. The size of the hash table is specified as a power of two. For example, if *hashSizeLog2* is 6, a 64-entry hash table is created.

If *sameNameOk* is FALSE, attempting to add a symbol with the same name and type as an already-existing symbol results in an error.

Memory for storing symbols as they are added to the symbol table will be allocated from the memory partition *symPartId*. The ID of the system memory partition is stored in the global variable **memSysPartId**, which is declared in **memLib.h**.

**RETURNS** Symbol table ID, or NULL if memory is insufficient.

**SEE ALSO** **symLib**

---

## ***symTblDelete()***

**NAME** *symTblDelete()* – delete a symbol table

**SYNOPSIS** **STATUS** *symTblDelete*  
(  
 SYMTAB\_ID *symTblId* /\* ID of symbol table to delete \*/  
)

**DESCRIPTION** This routine deletes a specified symbol table. It deallocates all associated memory, including the hash table, and marks the table as invalid.

Deletion of a table that still contains symbols results in ERROR. Successful deletion includes the deletion of the internal hash table and the deallocation of memory associated with the table. The table is marked invalid to prohibit any future references.

**RETURNS** OK, or ERROR if the symbol table ID is invalid.

**SEE ALSO** **symLib**

## *sysBusToLocalAdrs()*

|                    |                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>sysBusToLocalAdrs()</i> – convert a bus address to a local address                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <pre>STATUS sysBusToLocalAdrs (     int    adrsSpace, /* bus address space in which busAdrs resides */     char * busAdrs,  /* bus address to convert */     char * *pLocalAdrs /* where to return local address */ )</pre>                                         |
| <b>DESCRIPTION</b> | This routine gets the local address that accesses a specified bus memory address.                                                                                                                                                                                   |
| <b>NOTE</b>        | This is a generic page for a BSP-specific routine; this description contains general information only. To determine if this call is supported by your BSP, or for information specific to your BSP's version of this routine, see the reference pages for your BSP. |
| <b>RETURNS</b>     | OK, or ERROR if the address space is unknown or the mapping is not possible.                                                                                                                                                                                        |
| <b>SEE ALSO</b>    | <i>sysLib</i> , <i>sysLocalToBusAdrs()</i> , and BSP-specific reference pages for this routine                                                                                                                                                                      |

## **sysClkConnect()**

|                    |                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>sysClkConnect()</i> – connect a routine to the system clock interrupt                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <pre>STATUS sysClkConnect (     FUNCPTR routine, /* routine called at each system clock interrupt */     int      arg     /* argument with which to call routine */ )</pre>                                                                                            |
| <b>DESCRIPTION</b> | This routine specifies the interrupt service routine to be called at each clock interrupt. Normally, it is called from <i>usrRoot()</i> in <i>usrConfig.c</i> to connect <i>usrClock()</i> to the system clock interrupt.                                              |
| <b>NOTE</b>        | This is a generic page for a BSP-specific routine; this description contains general information only. To determine if this routine is supported by your BSP, or for information specific to your BSP's version of this routine, see the reference pages for your BSP. |
| <b>RETURN</b>      | OK, or ERROR if the routine cannot be connected to the interrupt.                                                                                                                                                                                                      |
| <b>SEE ALSO</b>    | <i>sysLib</i> , <i>intConnect()</i> , <i>usrClock()</i> , <i>sysClkEnable()</i> , and BSP-specific reference pages for this routine                                                                                                                                    |

## *sysLocalToBusAdrs()*

- NAME** *sysLocalToBusAdrs()* – convert a local address to a bus address
- SYNOPSIS**
- ```
STATUS sysLocalToBusAdrs
(
    int    adrsSpace, /* bus address space in which busAdrs resides */
    char * localAdrs, /* local address to convert */
    char * *pBusAdrs /* where to return bus address */
)
```
- DESCRIPTION** This routine gets the bus address that accesses a specified local memory address.
- NOTE** This is a generic page for a BSP-specific routine; this description contains general information only. To determine if this call is supported by your BSP, or for information specific to your BSP's version of this routine, see the reference pages for your BSP.
- RETURNS** OK, or ERROR if the address space is unknown or not mapped.
- SEE ALSO** *sysLib*, *sysBusToLocalAdrs()*, and BSP-specific reference pages for this routine

sysMailboxConnect()

- NAME** *sysMailboxConnect()* – connect a routine to the mailbox interrupt
- SYNOPSIS**
- ```
STATUS sysMailboxConnect
(
 FUNCPTR routine, /* routine called at each mailbox interrupt */
 int arg /* argument with which to call routine */
)
```
- DESCRIPTION** This routine specifies the interrupt service routine to be called at each mailbox interrupt.
- NOTE** This is a generic page for a BSP-specific routine; this description contains general information only. To determine if this call is supported by your BSP, or for information specific to your BSP's version of this routine, see the reference pages for your BSP.
- RETURNS** OK, or ERROR if the routine cannot be connected to the interrupt.
- SEE ALSO** *sysLib*, *intConnect()*, *sysMailboxEnable()*, and BSP-specific reference pages for this routine

| <b>NAME</b>        | <i>sysPhysMemTop()</i> – get the address of the top of memory                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <pre>char * sysPhysMemTop (void)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>This routine returns the address of the first missing byte of memory, which indicates the top of memory. Normally, the amount of physical memory is specified with the macro <code>LOCAL_MEM_SIZE</code>. BSPs that support run-time memory sizing do so only if the macro <code>LOCAL_MEM_AUTOSIZE</code> is defined. If not defined, then <code>LOCAL_MEM_SIZE</code> is assumed to be, and must be, the true size of physical memory.</p> <p>NOTE: Do not adjust <code>LOCAL_MEM_SIZE</code> to reserve memory for application use. See <i>sysMemTop()</i> for more information on reserving memory.</p> |
| <b>NOTE</b>        | This is a generic page for a BSP-specific routine; this description contains general information only. To determine if this call is supported by your BSP, or for information specific to your BSP's version of this routine, see the reference pages for your BSP.                                                                                                                                                                                                                                                                                                                                            |
| <b>RETURNS</b>     | The address of the top of physical memory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## ***sysProcNumGet()***

**NAME** *sysProcNumGet()* – get the processor number

**SYNOPSIS** `int sysProcNumGet (void)`

**DESCRIPTION** This routine returns the processor number for the CPU board, which is set with *sysProcNumSet()*.

**NOTE** This is a generic page for a BSP-specific routine; this description contains general information only. To determine if this call is supported by your BSP, or for information specific to your BSP's version of this routine, see the reference pages for your BSP.

**RETURNS** The processor number for the CPU board.

**SEE ALSO** *sysLib*, *sysProcNumSet()*, and BSP-specific reference pages for this routine

---

## ***sysProcNumSet()***

**NAME** *sysProcNumSet()* – set the processor number

**SYNOPSIS** `void sysProcNumSet  
(  
    int procNum /* processor number */  
)`

**DESCRIPTION** This routine sets the processor number for the CPU board. Processor numbers should be unique on a single backplane.

**NOTE** This is a generic page for a BSP-specific routine; this description contains general information only. To determine if this call is supported by your BSP, or for information specific to your BSP's version of this routine, see the reference pages for your BSP.

**RETURNS** N/A

| <b>DESCRIPTION</b> | <p>This is an example SCSI configuration routine.</p> <p>Most of the code found here is an example of how to declare a SCSI peripheral configuration. You must edit this routine to reflect the actual configuration of your SCSI bus. This example can also be found in <code>src/config/usrScsi.c</code>.</p> <p>If you are just getting started, you can test your hardware configuration by defining <code>SCSI_AUTO_CONFIG</code>, which will probe the bus and display all devices found. No device should have the same SCSI bus ID as your VxWorks SCSI port (default = 7), or the same as any other device. Check for proper bus termination.</p> <p>There are three configuration examples here. They demonstrate configuration of a SCSI hard disk (any type), an OMTI 3500 floppy disk, and a tape drive (any type).</p> |
| <b>Hard Disk</b>   | The hard disk is divided into two 32-Mbyte partitions and a third partition with the remainder of the disk. The first partition is initialized as a dosFs device. The second and third partitions are initialized as rt11Fs devices, each with 256 directory entries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

It is recommended that the first partition (**BLK\_DEV**) on a block device be a dosFs device, if the intention is eventually to boot VxWorks from the device. This will simplify the task considerably.

**Floppy Disk**

The floppy, since it is a removable medium device, is allowed to have only a single partition, and dosFs is the file system of choice for this device, since it facilitates media compatibility with IBM PC machines.

In contrast to the hard disk configuration, the floppy setup in this example is more intricate. Note that the *scsiPhysDevCreate()* call is issued twice. The first time is merely to get a "handle" to pass to *scsiModeSelect()*, since the default media type is sometimes inappropriate (in the case of generic SCSI-to-floppy cards). After the hardware is correctly configured, the handle is discarded via *scsiPhysDevDelete()*, after which the peripheral is correctly configured by a second call to *scsiPhysDevCreate()*. (Before the *scsiModeSelect()* call, the configuration information was incorrect.) Note that after the *scsiBlkDevCreate()* call, the correct values for *sectorsPerTrack* and *nHeads* must be set via *scsiBlkDevInit()*. This is necessary for IBM PC compatibility.

**Tape Drive**

The tape configuration is also somewhat complex because certain device parameters need to be turned off within VxWorks and the fixed-block size needs to be defined, assuming that the tape supports fixed blocks.

The last parameter to the *dosFsDevInit()* call is a pointer to a **DOS\_VOL\_CONFIG** structure. By specifying **NULL**, you are asking *dosFsDevInit()* to read this information off the disk in the drive. This may fail if no disk is present or if the disk has no valid dosFs directory. Should this be the case, you can use the *dosFsMkfs()* command to create a new directory on a disk. This routine uses default parameters (see **dosFsLib**) that may not be suitable for your application, in which case you should use *dosFsDevInit()* with a pointer to a valid **DOS\_VOL\_CONFIG** structure that you have created and initialized. If *dosFsDevInit()* is used, a *diskInit()* call should be made to write a new directory on the disk, if the disk is blank or disposable.

**NOTE**

The variable **pSbdFloppy** is global to allow the above calls to be made from the VxWorks shell, for example:

```
-> dosFsMkfs "/fd0/", pSbdFloppy
```

If a disk is new, use *diskFormat()* to format it.

**NOTE**

This is a generic page for a BSP-specific routine; this description contains general information only. To determine if this call is supported by your BSP, or for information specific to your BSP's version of this routine, see the reference pages for your BSP.

**RETURNS**

OK or ERROR.

|                    |                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>sysScsiInit()</i> – initialize an on-board SCSI port                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <code>STATUS sysScsiInit (void)</code>                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>This routine creates and initializes a SCSI control structure, enabling use of the on-board SCSI port. It also connects the proper interrupt service routine to the desired vector, and enables the interrupt at the desired level.</p> <p>If SCSI DMA is supported by the board and <code>INCLUDE_SCSI_DMA</code> is defined, the DMA is also initialized.</p> |
| <b>NOTE</b>        | <p>This is a generic page for a BSP-specific routine; this description contains general information only. To determine if this routine is supported by your BSP, or for information specific to your BSP's version of this routine, see the reference pages for your BSP.</p>                                                                                      |
| <b>RETURNS</b>     | OK, or ERROR if the control structure cannot be connected, the controller cannot be initialized, or the DMA's interrupt cannot be connected.                                                                                                                                                                                                                       |

## ***sysSerialHwInit2()***

|                    |                                                                                                                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>sysSerialHwInit2()</i> – connect BSP serial device interrupts                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <code>void sysSerialHwInit2 (void)</code>                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | This routine connects the BSP serial device interrupts. It is called from <i>sysHwInit2()</i> . Serial device interrupts could not be connected in <i>sysSerialHwInit()</i> because the kernel memory allocator was not initialized at that point, and <i>intConnect()</i> calls <i>malloc()</i> . |
| <b>NOTE</b>        | This is a generic page for a BSP-specific routine; this description contains general information only. |----------------------|-------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>system()</i> – pass a string to a command processor (Unimplemented) (ANSI) |
| <b>SYNOPSIS</b>      | <pre>int system (     const char * string /* pointer to string */ )</pre>     |
| <b>DESCRIPTION</b>   | This function is not applicable to VxWorks.                                   |
| <b>INCLUDE FILES</b> | <code>stdlib.h</code>                                                         |
| <b>RETURNS</b>       | OK, always.                                                                   |
| <b>SEE ALSO</b>      | <code>ansiStdlib</code>                                                       |

## **sysToMonitor()**

|                    |                                                                                                                                                                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>sysToMonitor()</i> – transfer control to the ROM monitor                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <pre>STATUS sysToMonitor (     int startType /* parameter passed to ROM to tell it how to boot */ )</pre>                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | This routine transfers control to the ROM monitor. Normally, it is called only by <i>reboot()</i> --which services CTRL+X--and by bus errors at interrupt level. However, in some circumstances, the user may wish to introduce a <i>startType</i> to enable special boot ROM facilities. |
| <b>NOTE</b>        | This is a generic page for a BSP-specific routine; this description contains general information only. To determine if this routine is supported by your BSP, or for information specific to your BSP's version of this routine, see the reference pages for your BSP.                    |
| <b>RETURNS</b>     | Does not return.                                                                                                                                                                                                                                                                          |
| <b>SEE ALSO</b>    | <i>sysLib</i> , and BSP-specific reference pages for this routine                                                                                                                                                                                                                         |

| <b>NAME</b>        | <i>tapeFsDevInit()</i> – associate a sequential device with tape volume functions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <pre>TAPE_VOL_DESC *tapeFsDevInit (     char *      volName,    /* volume name */     SEQ_DEV *   pSeqDev,    /* pointer to sequential device info */     TAPE_CONFIG * pTapeConfig /* pointer to tape config info */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>This routine takes a sequential device created by a device driver and defines it as a tape file system volume. As a result, when high-level I/O operations, such as <i>open()</i> and <i>write()</i>, are performed on the device, the calls will be routed through <b>tapeFsLib</b>.</p> <p>This routine associates <b>volName</b> with a device and installs it in the VxWorks I/O system-device table. The driver number used when the device is added to the table is that which was assigned to the tape library during <i>tapeFsInit()</i>. (The driver number is kept in the global variable <b>tapeFsDrvNum</b>.)</p> <p>The <b>SEQ_DEV</b> structure specified by <b>pSeqDev</b> contains configuration data describing the device and the addresses of the routines which are called to read blocks, write blocks, write file marks, reset the device, check device status, perform other I/O control functions (<i>ioctl()</i>), reserve and release devices, load and unload devices, and rewind devices. These</p> |

routines are not called until they are required by subsequent I/O operations. The TAPE\_CONFIG structure is used to define configuration parameters for the TAPE\_VOL\_DESC. The configuration parameters are defined and described in tapeFsLib.h.

- RETURNS** A pointer to the volume descriptor (TAPE\_VOL\_DESC), or NULL if there is an error.
- ERRNO** S\_tapeFsLib\_NO\_SEQ\_DEV, S\_tapeFsLib\_ILLEGAL\_TAPE\_CONFIG\_PARM
- SEE ALSO** tapeFsLib

## *tapeFsInit()*

- NAME** *tapeFsInit()* – initialize the tape volume library
- SYNOPSIS** `STATUS tapeFsInit ()`
- DESCRIPTION**

This routine initializes the tape volume library. It must be called exactly once, before any other routine in the library. Only one file descriptor per volume is assumed.

This routine also installs tape volume library routines in the VxWorks I/O system driver table. The driver number assigned to **tapeFsLib** is placed in the global variable **tapeFsDrvNum**. This number is later associated with system file descriptors opened to tapeFs devices.

To enable this initialization, simply call the routine *tapeFsDevInit()*, which automatically calls *tapeFsInit()* in order to initialize the tape file system.
- RETURNS** OK or ERROR.
- SEE ALSO** tapeFsLib

## *tapeFsReadyChange()*

- NAME** *tapeFsReadyChange()* – notify **tapeFsLib** of a change in ready status
- SYNOPSIS**

```
STATUS tapeFsReadyChange
(
 TAPE_VOL_DESC * pTapeVol /* pointer to volume descriptor */
)
```

|                    |                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | <p>This routine sets the volume descriptor state to <b>TAPE_VD_READY_CHANGED</b>. It should be called whenever a driver senses that a device has come on-line or gone off-line (for example, that a tape has been inserted or removed).</p> <p>After this routine has been called, the next attempt to use the volume results in an attempted remount.</p> |
| <b>RETURNS</b>     | OK if the read change status is set, or ERROR if the file descriptor is in use.                                                                                                                                                                                                                                                                            |
| <b>ERRNO</b>       | <b>S_tapeFsLib_FILE_DESCRIPTOR_BUSY</b>                                                                                                                                                                                                                                                                                                                    |

| <b>NAME</b>        | <b><i>tapeFsVolUnmount()</i></b> – disable a tape device volume                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <pre>STATUS tapeFsVolUnmount (     TAPE_VOL_DESC * pTapeVol /* pointer to volume descriptor */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>This routine is called when I/O operations on a volume are to be discontinued. This is commonly done before changing removable tape. All buffered data for the volume is written to the device (if possible), any open file descriptors are marked obsolete, and the volume is marked not mounted.</p> <p>Because this routine flushes data from memory to the physical device, it should not be used in situations where the tape-change is not recognized until after a new tape has been inserted. In these circumstances, use the ready-change mechanism. (See the manual entry for <b><i>tapeFsReadyChange()</i></b>.)</p> <p>This routine may also be called by issuing an <b><i>ioctl()</i></b> call using the <b>FIOUNMOUNT</b> function code.</p> |
| <b>RETURNS</b>     | OK, or ERROR if the routine cannot access the volume.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>taskActivate()</i> – activate a task that has been initialized                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <pre>STATUS taskActivate (     int tid /* task ID of task to activate */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | <p>This routine activates tasks created by <i>taskInit()</i>. Without activation, a task is ineligible for CPU allocation by the scheduler. The <i>tid</i> (task ID) argument is simply the address of the WIND_TCB for the task (the <i>taskInit()</i> <i>pTcb</i> argument), cast to an integer:</p> <pre>tid = (int) pTcb;</pre> <p>The <i>taskSpawn()</i> routine is built from <i>taskActivate()</i> and <i>taskInit()</i>. Tasks created by <i>taskSpawn()</i> do not require explicit task activation.</p> |
| <b>RETURNS</b>     | OK, or ERROR if the task cannot be activated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## ***taskDelay()***

|                 |                                                                                   |
|-----------------|-----------------------------------------------------------------------------------|
| <b>NAME</b>     | <i>taskDelay()</i> – delay a task from executing                                  |
| <b>SYNOPSIS</b> | <pre>STATUS taskDelay (     int ticks /* number of ticks to delay task */ )</pre> |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | This routine causes the calling task to relinquish the CPU for the duration specified (in ticks). This is commonly referred to as manual rescheduling, but it is also useful when waiting for some external condition that does not have an interrupt associated with it.<br><br>If the calling task receives a signal that is not being blocked or ignored, <i>taskDelay()</i> returns ERROR and sets <b>errno</b> to EINTR after the signal handler is run. |
| <b>RETURNS</b>     | OK, or ERROR if called from interrupt level or if the calling task receives a signal that is not blocked or ignored.                                                                                                                                                                                                                                                                                                                                          |
| <b>ERRNO</b>       | S_intLib_NOT_ISR_CALLABLE, EINTR                                                                                                                                                                                                                                                                                                                                                                                                                              |

|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>taskDeleteForce()</i> – delete a task without restriction                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <pre>STATUS taskDeleteForce (     int tid /* task ID of task to delete */ )</pre>                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | This routine deletes a task even if the task is protected from deletion. It is similar to <i>taskDelete()</i> . Upon deletion, all routines specified by <i>taskDeleteHookAdd()</i> will be called in the context of the deleting task.                                                                                                                                          |
| <b>CAVEATS</b>     | <p>This routine is intended as a debugging aid, and is generally inappropriate for applications. Disregarding a task's deletion protection could leave the the system in an unstable state or lead to system deadlock.</p> <p>The system does not protect against simultaneous <i>taskDeleteForce()</i> calls. Such a situation could leave the system in an unstable state.</p> |
| <b>RETURNS</b>     | OK, or ERROR if the task cannot be deleted.                                                                                                                                                                                                                                                                                                                                      |
| <b>ERRNO</b>       | S_intLib_NOT_ISR_CALLABLE, S_objLib_OBJ_DELETED, S_objLib_OBJ_UNAVAILABLE, S_objLib_OBJ_ID_ERROR                                                                                                                                                                                                                                                                                 |
| <b>SEE ALSO</b>    | <i>taskLib</i> , <i>taskDeleteHookAdd()</i> , <i>taskDelete()</i>                                                                                                                                                                                                                                                                                                                |

## ***taskDeleteHookAdd()***

|                    |                                                                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>taskDeleteHookAdd()</i> – add a routine to be called at every task delete                                                                                                               |
| <b>SYNOPSIS</b>    | <pre>STATUS taskDeleteHookAdd (     FUNCPTR deleteHook /* routine to be called when a task is deleted */ )</pre>                                                                           |
| <b>DESCRIPTION</b> | <p>This routine adds a specified routine to a list of routines that will be called whenever a task is deleted. The routine should be declared as follows:</p> <pre>void deleteHook (</pre> |

```
WIND_TCB *pTcb /* pointer to deleted task's WIND_TCB */
)
```

**RETURNS** OK, or ERROR if the table of task delete routines is full.

**SEE ALSO** *taskHookLib*, *taskDeleteHookDelete()*

---

## *taskDeleteHookDelete()*

**NAME** *taskDeleteHookDelete()* – delete a previously added task delete routine

**SYNOPSIS**

```
STATUS taskDeleteHookDelete
(
 FUNCPTR deleteHook /* routine to be deleted from list */
)
```

**DESCRIPTION** This routine removes a specified routine from the list of routines to be called at each task delete.

**RETURNS** OK, or ERROR if the routine is not in the table of task delete routines.

**SEE ALSO** *taskHookLib*, *taskDeleteHookAdd()*

---

## *taskDeleteHookShow()*

**NAME** *taskDeleteHookShow()* – show the list of task delete routines

**SYNOPSIS**

```
void taskDeleteHookShow (void)
```

**DESCRIPTION** This routine shows all the delete routines installed in the task delete hook table, in the order in which they were installed. Note that the delete routines will be run in reverse of the order in which they were installed.

**RETURNS** N/A

**SEE ALSO** *taskHookShow*, *taskDeleteHookAdd()*

## ***taskHookInit()***

---

|                    |                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>taskHookInit()</i> – initialize task hook facilities                                                                                                                               |
| <b>SYNOPSIS</b>    | <code>void taskHookInit (void)</code>                                                                                                                                                 |
| <b>DESCRIPTION</b> | This routine is a NULL routine called to configure the task hook package into the system. It is called automatically if the configuration macro <b>INCLUDE_TASK_HOOKS</b> is defined. |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                   |
| <b>SEE ALSO</b>    | <code>taskHookLib</code>                                                                                                                                                              |

## ***taskHookShowInit()***

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>taskHookShowInit()</i> – initialize the task hook show facility                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <code>void taskHookShowInit (void)</code>                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | <p>This routine links the task hook show facility into the VxWorks system. It is called automatically when the task hook show facility is configured into VxWorks using either of the following methods:</p> <ul style="list-style-type: none"><li>– If you use the configuration header files, define <b>INCLUDE_SHOW_ROUTINES</b> in <b>config.h</b>.</li><li>– If you use the Tornado project facility, select <b>INCLUDE_TASK_HOOK_SHOW</b>.</li></ul> |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SEE ALSO</b>    | <code>taskHookShow</code>                                                                                                                                                                                                                                                                                                                                                                                                                                  |

---

## ***taskIdDefault()***

**NAME** *taskIdDefault()* – set the default task ID

**SYNOPSIS**

```
int taskIdDefault
(
 int tid /* user supplied task ID; if 0, return default */
)
```

**DESCRIPTION** This routine maintains a global default task ID. This ID is used by libraries that want to allow a task ID argument to take on a default value when one is not explicitly supplied. If *tid* is not zero (i.e., the user did specify a task ID), the default ID is set to that value, and that value is returned. If *tid* is zero (i.e., the user did not specify a task ID), the default ID is not changed and its value is returned. Thus the value returned is always the last task ID the user specified.

**RETURNS** The most recent non-zero task ID.

**SEE ALSO** **taskInfo**, **dbgLib**, *VxWorks Programmer's Guide: Target Shell*, **windsh**, *Tornado User's Guide: Shell*

---

## ***taskIdListGet()***

**NAME** *taskIdListGet()* – get a list of active task IDs

**SYNOPSIS**

```
int taskIdListGet
(
 int idList[], /* array of task IDs to be filled in */
 int maxTasks /* max tasks idList can accommodate */
)
```

**DESCRIPTION** This routine provides the calling task with a list of all active tasks. An unsorted list of task IDs for no more than *maxTasks* tasks is put into *idList*.

**WARNING** Kernel rescheduling is disabled with **taskLock()** while tasks are filled into the *idList*. There is no guarantee that all the tasks are valid or that new tasks have not been created by the time this routine returns.

**RETURNS** The number of tasks put into the ID list.

**SEE ALSO** **taskInfo**

***taskIdSelf()***

---

***taskIdSelf()***

**NAME** *taskIdSelf()* – get the task ID of a running task

**SYNOPSIS** `int taskIdSelf (void)`

**DESCRIPTION** This routine gets the task ID of the calling task. The task ID will be invalid if called at interrupt level.

**RETURNS** The task ID of the calling task.

**SEE ALSO** `taskLib`

---

***taskIdVerify()***

**NAME** *taskIdVerify()* – verify the existence of a task

**SYNOPSIS** `STATUS taskIdVerify`  
`(`  
`int tid /* task ID */`  
`)`

**DESCRIPTION** This routine verifies the existence of a specified task by validating the specified ID as a task ID.

**RETURNS** OK, or ERROR if the task ID is invalid.

**ERRNO** `S_objLib_OBJ_ID_ERROR`

**SEE ALSO** `taskLib`

---

## *taskInfoGet()*

**NAME** *taskInfoGet()* – get information about a task

**SYNOPSIS**

```
STATUS taskInfoGet
(
 int tid, /* ID of task for which to get info */
 TASK_DESC * pTaskDesc /* task descriptor to be filled in */
)
```

**DESCRIPTION** This routine fills in a specified task descriptor (TASK\_DESC) for a specified task. The information in the task descriptor is, for the most part, a copy of information kept in the task control block (WIND\_TCB). The TASK\_DESC structure is useful for common information and avoids dealing directly with the unwieldy WIND\_TCB.

**NOTE** Examination of WIND\_TCBs should be restricted to debugging aids.

**RETURNS** OK, or ERROR if the task ID is invalid.

**SEE ALSO** *taskShow*

---

## *taskInit()*

**NAME** *taskInit()* – initialize a task with a stack at a specified address

**SYNOPSIS**

```
STATUS taskInit
(
 WIND_TCB * pTcb, /* address of new task's TCB */
 char * name, /* name of new task (stored at pStackBase) */
 int priority, /* priority of new task */
 int options, /* task option word */
 char * pStackBase, /* base of new task's stack */
 int stackSize, /* size (bytes) of stack needed */
 FUNCPTR entryPt, /* entry point of new task */
 int arg1, /* first of ten task args to pass to func */
 int arg2,
 int arg3,
 int arg4,
 int arg5,
 int arg6,
 int arg7,
```

***taskIsReady()***

```

 int arg8,
 int arg9,
 int arg10
)

```

**DESCRIPTION** This routine initializes user-specified regions of memory for a task stack and control block instead of allocating them from memory as *taskSpawn()* does. This routine will utilize the specified pointers to the `WIND_TCB` and stack as the components of the task. This allows, for example, the initialization of a static `WIND_TCB` variable. It also allows for special stack positioning as a debugging aid.

As in *taskSpawn()*, a task may be given a name. While *taskSpawn()* automatically names unnamed tasks, *taskInit()* permits the existence of tasks without names. The task ID required by other task routines is simply the address *pTcb*, cast to an integer.

Note that the task stack may grow up or down from `pStackBase`, depending on the target architecture.

Other arguments are the same as in *taskSpawn()*. Unlike *taskSpawn()*, *taskInit()* does not activate the task. This must be done by calling *taskActivate()* after calling *taskInit()*.

Normally, tasks should be started using *taskSpawn()* rather than *taskInit()*, except when additional control is required for task memory allocation or a separate task activation is desired.

**RETURNS** OK, or ERROR if the task cannot be initialized.

**ERRNO** `S_intLib_NOT_ISR_CALLABLE`, `S_objLib_OBJ_ID_ERROR`

**SEE ALSO** *taskLib*, *taskActivate()*, *taskSpawn()*

---

## ***taskIsReady()***

**NAME** *taskIsReady()* – check if a task is ready to run

**SYNOPSIS**

```

BOOL taskIsReady
(
 int tid /* task ID */
)

```

**DESCRIPTION** This routine tests the status field of a task to determine if it is ready to run.

**RETURNS** TRUE if the task is ready, otherwise FALSE.

**SEE ALSO** *taskInfo*

---

## *taskIsSuspended()*

**NAME** *taskIsSuspended()* – check if a task is suspended

**SYNOPSIS**

```
BOOL taskIsSuspended
(
 int tid /* task ID */
)
```

**DESCRIPTION** This routine tests the status field of a task to determine if it is suspended.

**RETURNS** TRUE if the task is suspended, otherwise FALSE.

**SEE ALSO** *taskInfo*

---

## *taskLock()*

**NAME** *taskLock()* – disable task rescheduling

**SYNOPSIS** `STATUS taskLock (void)`

**DESCRIPTION** This routine disables task context switching. The task that calls this routine will be the only task that is allowed to execute, unless the task explicitly gives up the CPU by making itself no longer ready. Typically this call is paired with *taskUnlock()*; together they surround a critical section of code. These preemption locks are implemented with a counting variable that allows nested preemption locks. Preemption will not be unlocked until *taskUnlock()* has been called as many times as *taskLock()*.

This routine does not lock out interrupts; use *intLock()* to lock out interrupts.

A *taskLock()* is preferable to *intLock()* as a means of mutual exclusion, because interrupt lock-outs add interrupt latency to the system.

A *semTake()* is preferable to *taskLock()* as a means of mutual exclusion, because preemption lock-outs add preemptive latency to the system.

The *taskLock()* routine is not callable from interrupt service routines.

**RETURNS** OK or ERROR.

**ERRNO** `S_objLib_OBJ_ID_ERROR`, `S_intLib_NOT_ISR_CALLABLE`

**taskName()**

|                    |                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>taskName()</i> – get the name associated with a task ID                                                                                           |
| <b>SYNOPSIS</b>    | <pre>char *taskName (     int tid /* ID of task whose name is to be found */ )</pre>                                                                 |
| <b>DESCRIPTION</b> | This routine returns a pointer to the name of a task of a specified ID, if the task has a name. If the task has no name, it returns an empty string. |
| <b>RETURNS</b>     | A pointer to the task name, or NULL if the task ID is invalid.                                                                                       |
| <b>SEE ALSO</b>    | <b>taskInfo</b>                                                                                                                                      |

---

**taskNameToId()**

|                    |                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>taskNameToId()</i> – look up the task ID associated with a task name                                                                                        |
| <b>SYNOPSIS</b>    | <pre>int taskNameToId (     char * name /* task name to look up */ )</pre>                                                                                     |
| <b>DESCRIPTION</b> | This routine returns the ID of the task matching a specified name. Referencing a task in this way is inefficient, since it involves a search of the task list. |
| <b>RETURNS</b>     | The task ID, or ERROR if the task is not found.                                                                                                                |
| <b>ERRNO</b>       | S_taskLib_NAME_NOT_FOUND                                                                                                                                       |
| <b>SEE ALSO</b>    | <b>taskInfo</b>                                                                                                                                                |

## *taskOptionsGet()*

**NAME** *taskOptionsGet()* – examine task options

**SYNOPSIS**

```
STATUS taskOptionsGet
(
 int tid, /* task ID */
 int * pOptions /* task's options */
)
```

**DESCRIPTION** This routine gets the current execution options of the specified task. The option bits returned by this routine indicate the following modes:

**VX\_FP\_TASK**  
execute with floating-point coprocessor support.

**VX\_PRIVATE\_ENV**  
include private environment support (see **envLib**).

**VX\_NO\_STACK\_FILL**  
do not fill the stack for use by *checkstack()*.

**VX\_UNBREAKABLE**  
do not allow breakpoint debugging.

For definitions, see **taskLib.h**.

**RETURNS** OK, or ERROR if the task ID is invalid.

**SEE ALSO** *taskInfo*, *taskOptionsSet()*

---

## *taskOptionsSet()*

**NAME** *taskOptionsSet()* – change task options

**SYNOPSIS**

```
STATUS taskOptionsSet
(
 int tid, /* task ID */
 int mask, /* bit mask of option bits to unset */
 int newOptions /* bit mask of option bits to set */
)
```

**DESCRIPTION** This routine changes the execution options of a task. The only option that can be changed after a task has been created is:

**VX\_UNBREAKABLE**  
do not allow breakpoint debugging.

For definitions, see **taskLib.h**.

**RETURNS** OK, or ERROR if the task ID is invalid.

**SEE ALSO** **taskInfo**, **taskOptionsGet()**

---

## ***taskPriorityGet()***

**NAME** ***taskPriorityGet()*** – examine the priority of a task

**SYNOPSIS**

```
STATUS taskPriorityGet
(
 int tid, /* task ID */
 int * pPriority /* return priority here */
)
```

**DESCRIPTION** This routine determines the current priority of a specified task. The current priority is copied to the integer pointed to by *pPriority*.

**RETURNS** OK, or ERROR if the task ID is invalid.

**ERRNO** S\_objLib\_OBJ\_ID\_ERROR

**SEE ALSO** **taskLib**, **taskPrioritySet()**

---

## ***taskPrioritySet()***

**NAME** ***taskPrioritySet()*** – change the priority of a task

**SYNOPSIS**

```
STATUS taskPrioritySet
(
 int tid, /* task ID */
 int newPriority /* new priority */
)
```

|                    |                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | This routine changes a task's priority to a specified priority. Priorities range from 0, the highest priority, to 255, the lowest priority. |
| <b>RETURNS</b>     | OK, or ERROR if the task ID is invalid.                                                                                                     |
| <b>ERRNO</b>       | S_taskLib_ILLEGAL_PRIORITY, S_objLib_OBJ_ID_ERROR                                                                                           |
| <b>SEE ALSO</b>    | taskLib, taskPriorityGet()                                                                                                                  |

---

## *taskRegsGet()*

|                    |                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>taskRegsGet()</i> – get a task's registers from the TCB                                                                                                                |
| <b>SYNOPSIS</b>    | <pre>STATUS taskRegsGet (     int      tid, /* task ID */     REG_SET * pRegs /* put register contents here */ )</pre>                                                    |
| <b>DESCRIPTION</b> | This routine gathers task information kept in the TCB. It copies the contents of the task's registers to the register structure <i>pRegs</i> .                            |
| <b>NOTE</b>        | This routine only works well if the task is known to be in a stable, non-executing state. Self-examination, for instance, is not advisable, as results are unpredictable. |
| <b>RETURNS</b>     | OK, or ERROR if the task ID is invalid.                                                                                                                                   |
| <b>SEE ALSO</b>    | taskInfo, taskSuspend(), taskRegsSet()                                                                                                                                    |

---

## *taskRegsSet()*

|                 |                                                                                                                             |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>     | <i>taskRegsSet()</i> – set a task's registers                                                                               |
| <b>SYNOPSIS</b> | <pre>STATUS taskRegsSet (     int      tid, /* task ID */     REG_SET * pRegs /* get register contents from here */ )</pre> |

- DESCRIPTION** This routine loads a specified register set *pRegs* into a specified task's TCB.
- NOTE** This routine only works well if the task is known not to be in the ready state. Suspending the task before changing the register set is recommended.
- RETURNS** OK, or ERROR if the task ID is invalid.
- SEE ALSO** *taskInfo*, *taskSuspend()*, *taskRegsGet()*

---

## ***taskRegsShow()***

**NAME** *taskRegsShow()* – display the contents of a task's registers

**SYNOPSIS**

```
void taskRegsShow
(
 int tid /* task ID */
)
```

**DESCRIPTION** This routine displays the register contents of a specified task on standard output.

**EXAMPLE** The following example displays the register of the shell task (68000 family):

```
-> taskRegsShow (taskNameToId ("tShell"))
d0 = 0 d1 = 0 d2 = 578fe d3 = 1
d4 = 3e84e1 d5 = 3e8568 d6 = 0 d7 = ffffffff
a0 = 0 a1 = 0 a2 = 4f06c a3 = 578d0
a4 = 3fffc4 a5 = 0 fp = 3e844c sp = 3e842c
sr = 3000 pc = 4f0f2
```

**RETURNS** N/A

**SEE ALSO** *taskShow*

---

## *taskRestart()*

|                    |                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>taskRestart()</i> – restart a task                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <pre>STATUS taskRestart (     int tid /* task ID of task to restart */ )</pre>                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | This routine "restarts" a task. The task is first terminated, and then reinitialized with the same ID, priority, options, original entry point, stack size, and parameters it had when it was terminated. Self-restarting of a calling task is performed by the exception task. The shell utilizes this routine to restart itself when aborted. |
| <b>NOTE</b>        | If the task has modified any of its start-up parameters, the restarted task will start with the changed values.                                                                                                                                                                                                                                 |
| <b>RETURNS</b>     | OK, or ERROR if the task ID is invalid or the task could not be restarted.                                                                                                                                                                                                                                                                      |
| <b>ERRNO</b>       | S_intLib_NOT_ISR_CALLABLE, S_objLib_OBJ_DELETED, S_objLib_OBJ_UNAVAILABLE, S_objLib_OBJ_ID_ERROR, S_smObjLib_NOT_INITIALIZED, S_memLib_NOT_ENOUGH_MEMORY, S_memLib_BLOCK_ERROR                                                                                                                                                                  |
| <b>SEE ALSO</b>    | taskLib                                                                                                                                                                                                                                                                                                                                         |

---

## *taskResume()*

|                    |                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>taskResume()</i> – resume a task                                                                         |
| <b>SYNOPSIS</b>    | <pre>STATUS taskResume (     int tid /* task ID of task to resume */ )</pre>                                |
| <b>DESCRIPTION</b> | This routine resumes a specified task. Suspension is cleared, and the task operates in the remaining state. |
| <b>RETURNS</b>     | OK, or ERROR if the task cannot be resumed.                                                                 |
| <b>ERRNO</b>       | S_objLib_OBJ_ID_ERROR                                                                                       |
| <b>SEE ALSO</b>    | taskLib                                                                                                     |

---

## *taskSafe()*

- NAME** *taskSafe()* – make the calling task safe from deletion
- SYNOPSIS** `STATUS taskSafe (void)`
- DESCRIPTION** This routine protects the calling task from deletion. Tasks that attempt to delete a protected task will block until the task is made unsafe, using *taskUnsafe()*. When a task becomes unsafe, the deleter will be unblocked and allowed to delete the task.
- The *taskSafe()* primitive utilizes a count to keep track of nested calls for task protection. When nesting occurs, the task becomes unsafe only after the outermost *taskUnsafe()* is executed.
- RETURNS** OK.
- SEE ALSO** *taskLib*, *taskUnsafe()*, *VxWorks Programmer's Guide: Basic OS*

---

## *taskShow()*

- NAME** *taskShow()* – display task information from TCBs
- SYNOPSIS** `STATUS taskShow`  
`(`  
`int tid, /* task ID */`  
`int level /* 0 = summary, 1 = details, 2 = all tasks */`  
`)`
- DESCRIPTION** This routine displays the contents of a task control block (TCB) for a specified task. If *level* is 1, it also displays task options and registers. If *level* is 2, it displays all tasks.
- The TCB display contains the following fields:

| Field  | Meaning                                                |
|--------|--------------------------------------------------------|
| NAME   | Task name                                              |
| ENTRY  | Symbol name or address where task began execution      |
| TID    | Task ID                                                |
| PRI    | Priority                                               |
| STATUS | Task status, as formatted by <i>taskStatusString()</i> |
| PC     | Program counter                                        |

| Field | Meaning                                                                    |
|-------|----------------------------------------------------------------------------|
| SP    | Stack pointer                                                              |
| ERRNO | Most recent error code for this task                                       |
| DELAY | If task is delayed, number of clock ticks remaining in delay (0 otherwise) |

**EXAMPLE**

The following example shows the TCB contents for the shell task:

```
-> taskShow tShell, 1
 NAME ENTRY TID PRI STATUS PC SP ERRNO DELAY

tShell _shell 20efcac 1 READY 201dc90 20ef980 0 0
stack: base 0x20efcac end 0x20ed59c size 9532 high 1452 margin 8080
options: 0x1e
VX_UNBREAKABLE VX_DEALLOC_STACK VX_FP_TASK VX_STDIO
D0 = 0 D4 = 0 A0 = 0 A4 = 0
D1 = 0 D5 = 0 A1 = 0 A5 = 203a084 SR = 3000
D2 = 0 D6 = 0 A2 = 0 A6 = 20ef9a0 PC = 2038614
D3 = 0 D7 = 0 A3 = 0 A7 = 20ef980
```

## *taskShowInit()*

**NAME**

**taskShowInit()** – initialize the task show routine facility

**SYNOPSIS**

**void taskShowInit (void)**

**DESCRIPTION**

This routine links the task show routines into the VxWorks system. It is called automatically when the task show facility is configured into VxWorks using either of the following methods:

- If you use the configuration header files, define **INCLUDE\_SHOW\_ROUTINES** in **config.h**.
- If you use the Tornado project facility, select **INCLUDE\_TASK\_SHOW**.

**RETURNS**

N/A

**SEE ALSO**

**taskShow**

**taskSpawn()**

---

**taskSpawn()****NAME** *taskSpawn()* – spawn a task

**SYNOPSIS**

```
int taskSpawn
(
 char * name, /* name of new task (stored at pStackBase) */
 int priority, /* priority of new task */
 int options, /* task option word */
 int stackSize, /* size (bytes) of stack needed plus name */
 FUNCPTR entryPt, /* entry point of new task */
 int arg1, /* 1st of 10 req'd task args to pass to func */
 int arg2,
 int arg3,
 int arg4,
 int arg5,
 int arg6,
 int arg7,
 int arg8,
 int arg9,
 int arg10
)
```

**DESCRIPTION** This routine creates and activates a new task with a specified priority and options and returns a system-assigned ID. See *taskInit()* and *taskActivate()* for the building blocks of this routine.

A task may be assigned a name as a debugging aid. This name will appear in displays generated by various system information facilities such as *i()*. The name may be of arbitrary length and content, but the current VxWorks convention is to limit task names to ten characters and prefix them with a "t". If *name* is specified as NULL, an ASCII name will be assigned to the task of the form "tn" where *n* is an integer which increments as new tasks are spawned.

The only resource allocated to a spawned task is a stack of a specified size *stackSize*, which is allocated from the system memory partition. Stack size should be an even integer. A task control block (TCB) is carved from the stack, as well as any memory required by the task name. The remaining memory is the task's stack and every byte is filled with the value 0xEE for the *checkStack()* facility. See the manual entry for *checkStack()* for stack-size checking aids.

The entry address *entryPt* is the address of the "main" routine of the task. The routine will be called once the C environment has been set up. The specified routine will be called with the ten given arguments. Should the specified main routine return, a call to *exit()* will automatically be made.

Note that ten (and only ten) arguments must be passed for the spawned function.

Bits in the options argument may be set to run with the following modes:

- VX\_FP\_TASK** (0x0008)  
execute with floating-point coprocessor support.
- VX\_PRIVATE\_ENV** (0x0080)  
include private environment support (see **envLib**).
- VX\_NO\_STACK\_FILL** (0x0100)  
do not fill the stack for use by *checkStack()*.
- VX\_UNBREAKABLE** (0x0002)  
do not allow breakpoint debugging.

See the definitions in **taskLib.h**.

- RETURNS** The task ID, or ERROR if memory is insufficient or the task cannot be created.
- ERRNO** **S\_intLib\_NOT\_ISR\_CALLABLE**, **S\_objLib\_OBJ\_ID\_ERROR**, **S\_smObjLib\_NOT\_INITIALIZED**, **S\_memLib\_NOT\_ENOUGH\_MEMORY**, **S\_memLib\_BLOCK\_ERROR**
- SEE ALSO** **taskLib**, *taskInit()*, *taskActivate()*, *sp()*, *VxWorks Programmer's Guide: Basic OS*

---

## ***taskSRInit()***

- NAME** *taskSRInit()* – initialize the default task status register (MIPS)
- SYNOPSIS**
- ```

ULONG taskSRInit
(
    ULONG newSRValue /* new default task status register */
)

```
- DESCRIPTION** This routine sets the default status register for system-wide tasks. All tasks will be spawned with the status register set to this value; thus, it must be called before *kernelInit()*.
- RETURNS** The previous value of the default status register.
- SEE ALSO** **taskArchLib**

taskSRSet()

NAME *taskSRSet()* – set the task status register (MC680x0, MIPS, i386/i486)

SYNOPSIS

```
STATUS taskSRSet
(
    int    tid, /* task ID */
    UINT16 sr  /* new SR */
)
```

DESCRIPTION This routine sets the status register of a task that is not running (i.e., the TCB must not be that of the calling task). Debugging facilities use this routine to set the trace bit in the status register of a task that is being single-stepped.

RETURNS OK, or ERROR if the task ID is invalid.

SEE ALSO *taskArchLib*

taskStatusString()

NAME *taskStatusString()* – get a task's status as a string

SYNOPSIS

```
STATUS taskStatusString
(
    int    tid, /* task to get string for */
    char * pString /* where to return string */
)
```

DESCRIPTION This routine deciphers the WIND task status word in the TCB for a specified task, and copies the appropriate string to *pString*.

The formatted string is one of the following:

| String | Meaning |
|---------------|----------------------------------------------------------------------------|
| READY | Task is not waiting for any resource other than the CPU. |
| PEND | Task is blocked due to the unavailability of some resource. |
| DELAY | Task is asleep for some duration. |
| SUSPEND | Task is unavailable for execution (but not suspended, delayed, or pended). |
| DELAY+S | Task is both delayed and suspended. |
| PEND+S | Task is both pended and suspended. |
| PEND+T | Task is pended with a timeout. |

| String | Meaning |
|----------|-----------------------------------------------------------------------|
| PEND+S+T | Task is pended with a timeout, and also suspended. |
| ...+I | Task has inherited priority (+I may be appended to any string above). |
| DEAD | Task no longer exists. |

EXAMPLE

```
-> taskStatusString (taskNameToId ("tShell"), xx=malloc (10))
new symbol "xx" added to symbol table.
-> printf ("shell status = <%s>\n", xx)
shell status = <READY>
```

RETURNS OK, or ERROR if the task ID is invalid.

SEE ALSO `taskShow`

taskSuspend()

NAME `taskSuspend()` – suspend a task

SYNOPSIS

```
STATUS taskSuspend
(
    int tid /* task ID of task to suspend */
)
```

DESCRIPTION This routine suspends a specified task. A task ID of zero results in the suspension of the calling task. Suspension is additive, thus tasks can be delayed and suspended, or pended and suspended. Suspended, delayed tasks whose delays expire remain suspended. Likewise, suspended, pended tasks that unblock remain suspended only.

Care should be taken with asynchronous use of this facility. The specified task is suspended regardless of its current state. The task could, for instance, have mutual exclusion to some system resource, such as the network * or system memory partition. If suspended during such a time, the facilities engaged are unavailable, and the situation often ends in deadlock.

This routine is the basis of the debugging and exception handling packages. However, as a synchronization mechanism, this facility should be rejected in favor of the more general semaphore facility.

RETURNS OK, or ERROR if the task cannot be suspended.

ERRNO `S_objLib_OBJ_ID_ERROR`

SEE ALSO `taskLib`

taskSwitchHookAdd()

NAME *taskSwitchHookAdd()* – add a routine to be called at every task switch

SYNOPSIS

```
STATUS taskSwitchHookAdd
(
    FUNCPTR switchHook /* routine to be called at every task switch */
)
```

DESCRIPTION This routine adds a specified routine to a list of routines that will be called at every task switch. The routine should be declared as follows:

```
void switchHook
(
    WIND_TCB *pOldTcb, /* pointer to old task's WIND_TCB */
    WIND_TCB *pNewTcb /* pointer to new task's WIND_TCB */
)
```

NOTE User-installed switch hooks are called within the kernel context. Therefore, switch hooks do not have access to all VxWorks facilities. The following routines can be called from within a task switch hook:

| Library | Routines |
|-------------------|------------------------------------------------------------------------------------------------------------------------|
| bLib | All routines |
| fppArchLib | <i>fppSave()</i> , <i>fppRestore()</i> |
| intLib | <i>intContext()</i> , <i>intCount()</i> , <i>intVecSet()</i> , <i>intVecGet()</i> |
| lstLib | All routines |
| mathALib | All routines, if <i>fppSave()</i> / <i>fppRestore()</i> are used |
| rngLib | All routines except <i>rngCreate()</i> |
| taskLib | <i>taskIdVerify()</i> , <i>taskIdDefault()</i> , <i>taskIsReady()</i> , <i>taskIsSuspended()</i> , <i>taskTcb()</i> |
| vxLib | <i>vxTas()</i> |

RETURNS OK, or ERROR if the table of task switch routines is full.

SEE ALSO *taskHookLib*, *taskSwitchHookDelete()*

taskSwitchHookDelete()

NAME *taskSwitchHookDelete()* – delete a previously added task switch routine

SYNOPSIS

```
STATUS taskSwitchHookDelete
(
    FUNCPTR switchHook /* routine to be deleted from list */
)
```

DESCRIPTION This routine removes the specified routine from the list of routines to be called at each task switch.

RETURNS OK, or ERROR if the routine is not in the table of task switch routines.

SEE ALSO *taskHookLib, taskSwitchHookAdd()*

taskSwitchHookShow()

NAME *taskSwitchHookShow()* – show the list of task switch routines

SYNOPSIS

```
void taskSwitchHookShow (void)
```

DESCRIPTION This routine shows all the switch routines installed in the task switch hook table, in the order in which they were installed.

RETURNS N/A

SEE ALSO *taskHookShow, taskSwitchHookAdd()*

taskTcb()

NAME *taskTcb()* – get the task control block for a task ID

SYNOPSIS

```
WIND_TCB *taskTcb
(
    int tid /* task ID */
)
```

taskUnlock()

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | This routine returns a pointer to the task control block (WIND_TCB) for a specified task. Although all task state information is contained in the TCB, users must not modify it directly. To change registers, for instance, use <i>taskRegsSet()</i> and <i>taskRegsGet()</i> . |
| RETURNS | A pointer to a WIND_TCB , or NULL if the task ID is invalid. |
| ERRNO | S_objLib_OBJ_ID_ERROR |
| SEE ALSO | taskLib |

taskUnlock()

| | |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>taskUnlock()</i> – enable task rescheduling |
| SYNOPSIS | STATUS <i>taskUnlock</i> (void) |
| DESCRIPTION | This routine decrements the preemption lock count. Typically this call is paired with <i>taskLock()</i> and concludes a critical section of code. Preemption will not be unlocked until <i>taskUnlock()</i> has been called as many times as <i>taskLock()</i> . When the lock count is decremented to zero, any tasks that were eligible to preempt the current task will execute. The <i>taskUnlock()</i> routine is not callable from interrupt service routines. |
| RETURNS | OK or ERROR. |
| ERRNO | S_intLib_NOT_ISR_CALLABLE |
| SEE ALSO | taskLib , <i>taskLock()</i> |

taskUnsafe()

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>taskUnsafe()</i> – make the calling task unsafe from deletion |
| SYNOPSIS | STATUS <i>taskUnsafe</i> (void) |
| DESCRIPTION | This routine removes the calling task's protection from deletion. Tasks that attempt to delete a protected task will block until the task is unsafe. When a task becomes unsafe, the deleter will be unblocked and allowed to delete the task. |

The *taskUnsafe()* primitive utilizes a count to keep track of nested calls for task protection. When nesting occurs, the task becomes unsafe only after the outermost *taskUnsafe()* is executed.

RETURNS OK.

SEE ALSO *taskLib*, *taskSafe()*, *VxWorks Programmer's Guide: Basic OS*

taskVarAdd()

NAME *taskVarAdd()* – add a task variable to a task

SYNOPSIS

```
STATUS taskVarAdd
(
    int    tid, /* ID of task to have new variable */
    int * pVar /* pointer to variable to be switched for task */
)
```

DESCRIPTION This routine adds a specified variable *pVar* (4-byte memory location) to a specified task's context. After calling this routine, the variable will be private to the task. The task can access and modify the variable, but the modifications will not appear to other tasks, and other tasks' modifications to that variable will not affect the value seen by the task. This is accomplished by saving and restoring the variable's initial value each time a task switch occurs to or from the calling task.

This facility can be used when a routine is to be spawned repeatedly as several independent tasks. Although each task will have its own stack, and thus separate stack variables, they will all share the same static and global variables. To make a variable *not* shareable, the routine can call *taskVarAdd()* to make a separate copy of the variable for each task, but all at the same physical address.

Note that task variables increase the task switch time to and from the tasks that own them. Therefore, it is desirable to limit the number of task variables that a task uses. One efficient way to use task variables is to have a single task variable that is a pointer to a dynamically allocated structure containing the task's private data.

EXAMPLE Assume that three identical tasks were spawned with a routine called *operator()*. All three use the structure **OP_GLOBAL** for all variables that are specific to a particular incarnation of the task. The following code fragment shows how this is set up:

taskVarDelete()

```

OP_GLOBAL *opGlobal; /* ptr to operator task's global variables */
void operator
(
    int opNum          /* number of this operator task */
)
{
    if (taskVarAdd (0, (int *)&opGlobal) != OK)
    {
        printErr ("operator%d: can't taskVarAdd opGlobal\n", opNum);
        taskSuspend (0);
    }
    if ((opGlobal = (OP_GLOBAL *) malloc (sizeof (OP_GLOBAL))) == NULL)
    {
        printErr ("operator%d: can't malloc opGlobal\n", opNum);
        taskSuspend (0);
    }
    ...
}

```

RETURNS OK, or ERROR if memory is insufficient for the task variable descriptor.

SEE ALSO *taskVarLib*, *taskVarDelete()*, *taskVarGet()*, *taskVarSet()*

taskVarDelete()

NAME *taskVarDelete()* – remove a task variable from a task

SYNOPSIS STATUS *taskVarDelete*

```

(
    int   tid, /* ID of task whose variable is to be removed */
    int * pVar /* pointer to task variable to be removed */
)

```

DESCRIPTION This routine removes a specified task variable, *pVar*, from the specified task's context. The private value of that variable is lost.

RETURNS OK, or ERROR if the task variable does not exist for the specified task.

SEE ALSO *taskVarLib*, *taskVarAdd()*, *taskVarGet()*, *taskVarSet()*

taskVarGet()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>taskVarGet()</i> – get the value of a task variable |
| SYNOPSIS | <pre>int taskVarGet (int tid, /* ID of task whose task variable is to be retrieved */ int * pVar /* pointer to task variable */)</pre> |
| DESCRIPTION | This routine returns the private value of a task variable for a specified task. The specified task is usually not the calling task, which can get its private value by directly accessing the variable. This routine is provided primarily for debugging purposes. |
| RETURNS | The private value of the task variable, or ERROR if the task is not found or it does not own the task variable. |
| SEE ALSO | <i>taskVarLib</i> , <i>taskVarAdd()</i> , <i>taskVarDelete()</i> , <i>taskVarSet()</i> |

taskVarInfo()

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>taskVarInfo()</i> – get a list of task variables of a task |
| SYNOPSIS | <pre>int taskVarInfo (int tid, /* ID of task whose task variable is to be set */ TASK_VAR varList[], /* array to hold task variable addresses */ int maxVars /* maximum variables varList can accommodate */)</pre> |
| DESCRIPTION | This routine provides the calling task with a list of all of the task variables of a specified task. The unsorted array of task variables is copied to <i>varList</i> . |
| CAVEATS | Kernel rescheduling is disabled with <i>taskLock()</i> while task variables are looked up. There is no guarantee that all the task variables are still valid or that new task variables have not been created by the time this routine returns. |
| RETURNS | The number of task variables in the list. |
| SEE ALSO | <i>taskVarLib</i> |

taskVarInit()

taskVarInit()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>taskVarInit()</i> – initialize the task variables facility |
| SYNOPSIS | STATUS <code>taskVarInit (void)</code> |
| DESCRIPTION | <p>This routine initializes the task variables facility. It installs task switch and delete hooks used for implementing task variables. If <i>taskVarInit()</i> is not called explicitly, <i>taskVarAdd()</i> will call it automatically when the first task variable is added.</p> <p>After the first invocation of this routine, subsequent invocations have no effect.</p> |
| WARNING | <p>Order dependencies in task delete hooks often involve task variables. If a facility uses task variables and has a task delete hook that expects to use those task variables, the facility's delete hook must run before the task variables' delete hook. Otherwise, the task variables will be deleted by the time the facility's delete hook runs.</p> <p>VxWorks is careful to run the delete hooks in reverse of the order in which they were installed. Any facility that has a delete hook that will use task variables can guarantee proper ordering by calling <i>taskVarInit()</i> before adding its own delete hook.</p> <p>Note that this is not an issue in normal use of task variables. The issue only arises when adding another task delete hook that uses task variables.</p> <p>Caution should also be taken when adding task variables from within create hooks. If the task variable package has not been installed via <i>taskVarInit()</i>, the create hook attempts to create a create hook, and that may cause system failure. To avoid this situation, <i>taskVarInit()</i> should be called during system initialization from the root task, <i>usrRoot()</i>, in <i>usrConfig.c</i>.</p> |
| RETURNS | OK, or ERROR if the task switch/delete hooks could not be installed. |
| SEE ALSO | <i>taskVarLib</i> |

taskVarSet()

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>taskVarSet()</i> – set the value of a task variable |
| SYNOPSIS | <pre>STATUS taskVarSet (int tid, /* ID of task whose task variable is to be set */ int * pVar, /* pointer to task variable to be set for this task */ int value /* new value of task variable */)</pre> |
| DESCRIPTION | This routine sets the private value of the task variable for a specified task. The specified task is usually not the calling task, which can set its private value by directly modifying the variable. This routine is provided primarily for debugging purposes. |
| RETURNS | OK, or ERROR if the task is not found or it does not own the task variable. |
| SEE ALSO | <i>taskVarLib</i> , <i>taskVarAdd()</i> , <i>taskVarDelete()</i> , <i>taskVarGet()</i> |

tcicInit()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>tcicInit()</i> – initialize the TCIC chip |
| SYNOPSIS | <pre>STATUS tcicInit (int ioBase, /* IO base address */ int intVec, /* interrupt vector */ int intLevel, /* interrupt level */ FUNCPTR showRtn /* show routine */)</pre> |
| DESCRIPTION | This routine initializes the TCIC chip. |
| RETURNS | OK, or ERROR if the TCIC chip cannot be found. |
| SEE ALSO | <i>tcic</i> |

tcicShow()

NAME *tcicShow()* – show all configurations of the TCIC chip

SYNOPSIS

```
void tcicShow
(
    int sock /* socket no. */
)
```

DESCRIPTION This routine shows all configurations of the TCIC chip.

RETURNS N/A

SEE ALSO *tcicShow*

tcpDebugShow()

NAME *tcpDebugShow()* – display debugging information for the TCP protocol

SYNOPSIS

```
void tcpDebugShow
(
    int numPrint, /* no. of entries to print, default (0) = 20 */
    int verbose /* 1 = verbose */
)
```

DESCRIPTION This routine displays debugging information for the TCP protocol. To include TCP debugging facilities, define `INCLUDE_TCP_DEBUG` when building the system image. To enable information gathering, turn on the `SO_DEBUG` option for the relevant socket(s).

RETURNS N/A

SEE ALSO *tcpShow*

tcpShowInit()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>tcpShowInit()</i> – initialize TCP show routines |
| SYNOPSIS | <code>void tcpShowInit (void)</code> |
| DESCRIPTION | This routine links the TCP show facility into the VxWorks system. These routines are included automatically if <code>INCLUDE_NET_SHOW</code> and <code>INCLUDE_TCP</code> are defined in <code>configAll.h</code> . |
| RETURNS | N/A |
| SEE ALSO | <code>tcpShow</code> |

tcpstatShow()

| | |
|--------------------|--------------------------------------------------------------------|
| NAME | <i>tcpstatShow()</i> – display all statistics for the TCP protocol |
| SYNOPSIS | <code>void tcpstatShow (void)</code> |
| DESCRIPTION | This routine displays detailed statistics for the TCP protocol. |
| RETURNS | N/A |
| SEE ALSO | <code>tcpShow</code> |

tcw()

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>tcw()</i> – return the contents of the <code>tcw</code> register (i960) |
| SYNOPSIS | <pre>int tcw (int taskId /* task ID, 0 means default task */)</pre> |
| DESCRIPTION | This command extracts the contents of the <code>tcw</code> register from the TCB of a specified task. If <i>taskId</i> is omitted or 0, the current default task is assumed. |

td()

- RETURNS** The contents of the **tcw** register.
- SEE ALSO** **dbgArchLib**, *VxWorks Programmer's Guide: Target Shell*

td()

- NAME** *td()* – delete a task
- SYNOPSIS**
- ```
void td
(
 int taskNameOrId /* task name or task ID */
)
```
- DESCRIPTION** This command deletes a specified task. It simply calls *taskDelete()*.
- RETURNS** N/A
- SEE ALSO** **usrLib**, *taskDelete()*, *VxWorks Programmer's Guide: Target Shell*, **windsh**, *Tornado User's Guide: Shell*

---

## ***telnetd()***

- NAME** *telnetd()* – VxWorks telnet daemon
- SYNOPSIS**
- ```
void telnetd (void)
```
- DESCRIPTION** This routine enables remote users to log in to VxWorks over the network via the telnet protocol. It is spawned by *telnetInit()*, which should be called at boot time.
- Remote telnet requests will cause **stdin**, **stdout**, and **stderr** to be stolen away from the console. When the remote user disconnects, **stdin**, **stdout**, and **stderr** are restored, and the shell is restarted.
- The telnet daemon requires the existence of a pseudo-terminal device, which is created by *telnetInit()* before *telnetd()* is spawned. The *telnetd()* routine creates two additional processes, **tTelnetInTask** and **tTelnetOutTask**, whenever a remote user is logged in. These processes exit when the remote connection is terminated.
- RETURNS** N/A
- SEE ALSO** **telnetLib**

telnetInit()

NAME *telnetInit()* – initialize the telnet daemon

SYNOPSIS `void telnetInit (void)`

DESCRIPTION This routine initializes the telnet facility, which supports remote login to the VxWorks shell via the telnet protocol. It creates a pty device and spawns the telnet daemon. It is called automatically when the configuration macro `INCLUDE_TELNET` is defined.

RETURNS N/A

SEE ALSO `telnetLib`

tftpCopy()

NAME *tftpCopy()* – transfer a file via TFTP

SYNOPSIS `STATUS tftpCopy`

```
(
    char * pHost,      /* host name or address */
    int   port,       /* optional port number */
    char * pFilename, /* remote filename */
    char * pCommand,  /* TFTP command */
    char * pMode,     /* TFTP transfer mode */
    int   fd          /* fd to put/get data */
)
```

DESCRIPTION This routine transfers a file using the TFTP protocol to or from a remote system. *pHost* is the remote server name or Internet address. A non-zero value for *port* specifies an alternate TFTP server port (zero means use default TFTP port number (69)). *pFilename* is the remote filename. *pCommand* specifies the TFTP command, which can be either "put" or "get". *pMode* specifies the mode of transfer, which can be "ascii", "netascii", "binary", "image", or "octet".

fd is a file descriptor from which to read/write the data from or to the remote system. For example, if the command is "get", the remote data will be written to *fd*. If the command is "put", the data to be sent is read from *fd*. The caller is responsible for managing *fd*. That is, *fd* must be opened prior to calling *tftpCopy()* and closed up on completion.

- EXAMPLE** The following sequence gets an ASCII file "/folk/vw/xx.yy" on host "congo" and stores it to a local file called "localfile":
- ```
-> fd = open ("localfile", 0x201, 0644)
-> tftpdCopy ("congo", 0, "/folk/vw/xx.yy", "get", "ascii", fd)
-> close (fd)
```
- RETURNS** OK, or ERROR if unsuccessful.
- ERRNO** S\_tftpdLib\_INVALID\_COMMAND
- SEE ALSO** tftpdLib, ftpLib

---

## ***tftpdDirectoryAdd()***

- NAME** *tftpdDirectoryAdd()* – add a directory to the access list
- SYNOPSIS**
- ```
STATUS tftpdDirectoryAdd
(
    char * fileName /* name of directory to add to access list */
)
```
- DESCRIPTION** This routine adds the specified directory name to the access list for the TFTP server.
- RETURNS** N/A
- SEE ALSO** tftpdLib

tftpdDirectoryRemove()

- NAME** *tftpdDirectoryRemove()* – delete a directory from the access list
- SYNOPSIS**
- ```
STATUS tftpdDirectoryRemove
(
 char * fileName /* name of directory to add to access list */
)
```
- DESCRIPTION** This routine deletes the specified directory name from the access list for the TFTP server.

RETURNS N/A

SEE ALSO *tftpdLib*

---

## *tftpdInit()*

NAME *tftpdInit()* – initialize the TFTP server task

SYNOPSIS

```
STATUS tftpdInit
(
 int stackSize, /* stack size for the tftpdTask */
 int nDirectories, /* number of directories allowed read */
 char * *directoryNames, /* array of dir names */
 BOOL noControl, /* TRUE if no access control required */
 int maxConnections
)
```

DESCRIPTION This routine will spawn a new TFTP server task, if one does not already exist. If a TFTP server task is running already, *tftpdInit()* will simply return without creating a new task. It will simply report whether a new TFTP task was successfully spawned. The argument *stackSize* can be specified to change the default stack size for the TFTP server task. The default size is set in the global variable *tftpdTaskStackSize*.

RETURNS OK, or ERROR if a new TFTP task cannot be created.

## *tftpdTask()*

NAME *tftpdTask()* – TFTP server daemon task

SYNOPSIS

```
STATUS tftpdTask
(
 int nDirectories, /* number of dirs allowed access */
 char * *directoryNames, /* array of directory names */
 int maxConnections /* max number of simultan. connects */
)
```

**tftpGet()**

|                    |                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | This routine processes incoming TFTP client requests by spawning a new task for each connection that is set up.<br><br>This routine is called by <i>tftpdInit()</i> . |
| <b>RETURNS</b>     | OK, or ERROR if the task returns unexpectedly.                                                                                                                        |

## *tftpInfoShow()*

|                    |                                                                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>tftpInfoShow()</i> – get TFTP status information                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <pre>STATUS tftpInfoShow (     TFTP_DESC * pTftpDesc /* TFTP descriptor */ )</pre>                                                                                                                                                                    |
| <b>DESCRIPTION</b> | This routine prints information associated with TFTP descriptor <i>pTftpDesc</i> .                                                                                                                                                                    |
| <b>EXAMPLE</b>     | A call to <i>tftpInfoShow()</i> might look like:<br><pre>-&gt; tftpInfoShow (tftpDesc)     Connected to yuba [69]     Mode: netascii Verbose: off Tracing: off     Rexmt-interval: 5 seconds, Max-timeout: 25 seconds     value = 0 = 0x0 -&gt;</pre> |
| <b>RETURNS</b>     | OK, or ERROR if unsuccessful.                                                                                                                                                                                                                         |
| <b>ERRNO</b>       | S_tftpLib_INVALID_DESCRIPTOR                                                                                                                                                                                                                          |
| <b>SEE ALSO</b>    | <i>tftpLib</i>                                                                                                                                                                                                                                        |

---

## *tftpInit()*

|                    |                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>tftpInit()</i> – initialize a TFTP session                                                                                              |
| <b>SYNOPSIS</b>    | <pre>TFTP_DESC * tftpInit (void)</pre>                                                                                                     |
| <b>DESCRIPTION</b> | This routine initializes a TFTP session by allocating and initializing a TFTP descriptor. It sets the default transfer mode to "netascii". |
| <b>RETURNS</b>     | A pointer to a TFTP descriptor if successful, otherwise NULL.                                                                              |
| <b>SEE ALSO</b>    | <i>tftpLib</i>                                                                                                                             |

---

## ***tftpModeSet()***

**NAME** *tftpModeSet()* – set the TFTP transfer mode

**SYNOPSIS**

```
STATUS tftpModeSet
(
 TFTP_DESC * pTftpDesc, /* TFTP descriptor */
 char * pMode /* TFTP transfer mode */
)
```

**DESCRIPTION** This routine sets the transfer mode associated with the TFTP descriptor *pTftpDesc*. *pMode* specifies the transfer mode, which can be "netascii", "binary", "image", or "octet". Although recognized, these modes actually translate into either octet or netascii.

**RETURNS** OK, or ERROR if unsuccessful.

**ERRNO** S\_tftpLib\_INVALID\_DESCRIPTOR  
S\_tftpLib\_INVALID\_ARGUMENT  
S\_tftpLib\_INVALID\_MODE

**SEE ALSO** *tftpLib*

---

## ***tftpPeerSet()***

**NAME** *tftpPeerSet()* – set the TFTP server address

**SYNOPSIS**

```
STATUS tftpPeerSet
(
 TFTP_DESC * pTftpDesc, /* TFTP descriptor */
 char * pHostname, /* server name/address */
 int port /* port number */
)
```

**DESCRIPTION** This routine sets the TFTP server (peer) address associated with the TFTP descriptor *pTftpDesc*. *pHostname* is either the TFTP server name (e.g., "congo") or the server Internet address (e.g., "90.3"). A non-zero value for *port* specifies the server port number (zero means use the default TFTP server port number (69)).

**RETURNS** OK, or ERROR if unsuccessful.

**ERRNO** S\_tftpLib\_INVALID\_DESCRIPTOR  
S\_tftpLib\_INVALID\_ARGUMENT  
S\_tftpLib\_UNKNOWN\_HOST

**SEE ALSO** tftpLib

---

## *tftpPut()*

**NAME** *tftpPut()* – put a file to a remote system

**SYNOPSIS**

```
STATUS tftpPut
(
 TFTP_DESC * pTftpDesc, /* TFTP descriptor */
 char * pFilename, /* remote filename */
 int fd, /* file descriptor */
 int clientOrServer /* which side is calling */
)
```

**DESCRIPTION** This routine puts data from a local file (descriptor) to a file on the remote system. *pTftpDesc* is a pointer to the TFTP descriptor. *pFilename* is the remote filename. *fd* is the file descriptor from which it gets the data. A call to *tftpPeerSet()* must be made prior to calling this routine.

**RETURNS** OK, or ERROR if unsuccessful.

**ERRNO** S\_tftpLib\_INVALID\_DESCRIPTOR  
S\_tftpLib\_INVALID\_ARGUMENT  
S\_tftpLib\_NOT\_CONNECTED

**SEE ALSO** tftpLib

---

## *tftpQuit()*

**NAME** *tftpQuit()* – quit a TFTP session

**SYNOPSIS**

```
STATUS tftpQuit
(
 TFTP_DESC * pTftpDesc /* TFTP descriptor */
)
```

|                    |                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | This routine closes a TFTP session associated with the TFTP descriptor <i>pTftpDesc</i> . |
| <b>RETURNS</b>     | OK, or ERROR if unsuccessful.                                                             |
| <b>ERRNO</b>       | S_tftpLib_INVALID_DESCRIPTOR                                                              |
| <b>SEE ALSO</b>    | tftpLib                                                                                   |

---

## *tftpSend()*

**NAME** *tftpSend()* – send a TFTP message to the remote system

**SYNOPSIS**

```
int tftpSend
(
 TFTP_DESC * pTftpDesc, /* TFTP descriptor */
 TFTP_MSG * pTftpMsg, /* TFTP send message */
 int sizeMsg, /* send message size */
 TFTP_MSG * pTftpReply, /* TFTP reply message */
 int opReply, /* reply opcode */
 int blockReply, /* reply block number */
 int * pPort /* return port number */
)
```

**DESCRIPTION** This routine sends *sizeMsg* bytes of the passed message *pTftpMsg* to the remote system associated with the TFTP descriptor *pTftpDesc*. If *pTftpReply* is not NULL, *tftpSend()* tries to get a reply message with a block number *blockReply* and an opcode *opReply*. If *pPort* is NULL, the reply message must come from the same port to which the message was sent. If *pPort* is not NULL, the port number from which the reply message comes is copied to this variable.

**RETURNS** The size of the reply message, or ERROR.

**ERRNO** S\_tftpLib\_TIMED\_OUT  
S\_tftpLib\_TFTP\_ERROR

**SEE ALSO** tftpLib

---

## *tftpXfer()*

**NAME** *tftpXfer()* – transfer a file via TFTP using a stream interface

**SYNOPSIS**

```
STATUS tftpXfer
(
 char * pHost, /* host name or address */
 int port, /* port number */
 char * pFilename, /* remote filename */
 char * pCommand, /* TFTP command */
 char * pMode, /* TFTP transfer mode */
 int * pDataDesc, /* return data desc. */
 int * pErrorDesc /* return error desc. */
)
```

**DESCRIPTION** This routine initiates a transfer to or from a remote file via TFTP. It spawns a task to perform the TFTP transfer and returns a descriptor from which the data can be read (for "get") or to which it can be written (for "put") interactively. The interface for this routine is similar to *ftpXfer()* in **ftpLib**.

*pHost* is the server name or Internet address. A non-zero value for *ports* specifies an alternate TFTP server port number (zero means use default TFTP port number (69)). *pFilename* is the remote filename. *pCommand* specifies the TFTP command. The command can be either "put" or "get".

The *tftpXfer()* routine returns a data descriptor, in *pDataDesc*, from which the TFTP data is read (for "get") or to which it is written (for "put"). An error status descriptor gets returned in the variable *pErrorDesc*. If an error occurs during the TFTP transfer, an error string can be read from this descriptor. After returning successfully from *tftpXfer()*, the calling application is responsible for closing both descriptors.

If there are delays in reading or writing the data descriptor, it is possible for the TFTP transfer to time out.

**EXAMPLE** The following code demonstrates how *tftpXfer()* may be used:

```
#include "tftpLib.h"
#define BUFFERSIZE 512
int dataFd;
int errorFd;
int num;
char buf [BUFFERSIZE + 1];
if (tftpXfer ("congo", 0, "/usr/fred", "get", "ascii", &dataFd,
 &errorFd) == ERROR)
 return (ERROR);
while ((num = read (dataFd, buf, sizeof (buf))) > 0)
```

**ti()**

```

 {

 }
 close (dataFd);
 num = read (errorFd, buf, BUFFERSIZE);
 if (num > 0)
 {
 buf [num] = '\0';
 printf ("YIKES! An error occurred!:%s\n", buf);

 }
 close (errorFd);

```

**RETURNS** OK, or ERROR if unsuccessful.

**ERRNO** S\_ftpLib\_INVALID\_ARGUMENT

**SEE ALSO** tftpLib, ftpLib

**ti()**

**NAME** *ti()* – print complete information from a task’s TCB

**SYNOPSIS**

```

void ti
(
 int taskNameOrId /* task name or task ID; 0 = use default */
)

```

**DESCRIPTION** This command prints the task control block (TCB) contents, including registers, for a specified task. If *taskNameOrId* is omitted or zero, the last task referenced is assumed.

The *ti()* routine uses *taskShow()*; see the documentation for *taskShow()* for a description of the output format.

**EXAMPLE** The following shows the TCB contents for the shell task:

```

-> ti
 NAME ENTRY TID PRI STATUS PC SP ERRNO DELAY

tShell _shell 20efcac 1 READY 201dc90 20ef980 0 0

```

**RETURNS** N/A**SEE ALSO** *usrLib, taskShow()*, *VxWorks Programmer's Guide: Target Shell*, *windsh*, *Tornado User's Guide: Shell*

---

## *tickAnnounce()*

**NAME** *tickAnnounce()* – announce a clock tick to the kernel**SYNOPSIS** `void tickAnnounce (void)`**DESCRIPTION** This routine informs the kernel of the passing of time. It should be called from an interrupt service routine that is connected to the system clock. The most common frequencies are 60Hz or 100Hz. Frequencies in excess of 600Hz are an inefficient use of processor power because the system will spend most of its time advancing the clock. By default, this routine is called by *usrClock()* in *usrConfig.c*.**RETURNS** N/A**SEE ALSO** *tickLib, kernelLib, taskLib, semLib, wdLib*, *VxWorks Programmer's Guide: Basic OS*

---

## *tickGet()*

**NAME** *tickGet()* – get the value of the kernel's tick counter**SYNOPSIS** `ULONG tickGet (void)`**DESCRIPTION** This routine returns the current value of the tick counter. This value is set to zero at startup, incremented by *tickAnnounce()*, and can be changed using *tickSet()*.**RETURNS** The most recent *tickSet()* value, plus all *tickAnnounce()* calls since.**SEE ALSO** *tickLib, tickSet(), tickAnnounce()*

***tickSet()***

***tickSet()***

|                    |                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>tickSet()</i> – set the value of the kernel’s tick counter                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <pre>void tickSet (     ULONG ticks /* new time in ticks */ )</pre>                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | This routine sets the internal tick counter to a specified value in ticks. The new count will be reflected by <i>tickGet()</i> , but will not change any delay fields or timeouts selected for any tasks. For example, if a task is delayed for ten ticks, and this routine is called to advance time, the delayed task will still be delayed until ten <i>tickAnnounce()</i> calls have been made. |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SEE ALSO</b>    | <i>tickLib</i> , <i>tickGet()</i> , <i>tickAnnounce()</i>                                                                                                                                                                                                                                                                                                                                           |

---

***time()***

|                      |                                                                                                                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>time()</i> – determine the current calendar time (ANSI)                                                                                                                                                   |
| <b>SYNOPSIS</b>      | <pre>time_t time (     time_t * timer /* calendar time in seconds */ )</pre>                                                                                                                                 |
| <b>DESCRIPTION</b>   | This routine returns the implementation’s best approximation of current calendar time in seconds. If <i>timer</i> is non-NULL, the return value is also copied to the location to which <i>timer</i> points. |
| <b>INCLUDE FILES</b> | <i>time.h</i>                                                                                                                                                                                                |
| <b>RETURNS</b>       | The current calendar time in seconds, or ERROR (-1) if the calendar time is not available.                                                                                                                   |
| <b>SEE ALSO</b>      | <i>ansiTime</i> , <i>clock_gettime()</i>                                                                                                                                                                     |

## *timer\_cancel()*

|                    |                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>timer_cancel()</i> – cancel a timer                                                       |
| <b>SYNOPSIS</b>    | <pre>int timer_cancel (     timer_t timerid /* timer ID */ )</pre>                           |
| <b>DESCRIPTION</b> | This routine is a shorthand method of invoking <i>timer_settime()</i> , which stops a timer. |
| <b>NOTE</b>        | Non-POSIX.                                                                                   |
| <b>RETURNS</b>     | 0 (OK), or -1 (ERROR) if <i>timerid</i> is invalid.                                          |
| <b>ERRNO</b>       | EINVAL                                                                                       |
| <b>SEE ALSO</b>    | timerLib                                                                                     |

## *timer\_connect()*

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>timer_connect()</i> – connect a user routine to the timer signal                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <pre>int timer_connect (     timer_t    timerid, /* timer ID */     VOIDFUNCPTR routine, /* user routine */     int        arg      /* user argument */ )</pre>                                                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b> | <p>This routine sets the specified <i>routine</i> to be invoked with <i>arg</i> when fielding a signal indicated by the timer's <i>evp</i> signal number, or if <i>evp</i> is NULL, when fielding the default signal (SIGALRM).</p> <p>The signal handling routine should be declared as:</p> <pre>void my_handler (     timer_t timerid, /* expired timer ID */     int arg          /* user argument */ )</pre> |

***timer\_create()***

|                 |                                                                                  |
|-----------------|----------------------------------------------------------------------------------|
| <b>NOTE</b>     | Non-POSIX.                                                                       |
| <b>RETURNS</b>  | 0 (OK), or -1 (ERROR) if the timer is invalid or cannot bind the signal handler. |
| <b>ERRNO</b>    | EINVAL                                                                           |
| <b>SEE ALSO</b> | <b>timerLib</b>                                                                  |

---

***timer\_create()***

**NAME** *timer\_create()* – allocate a timer using the specified clock for a timing base (POSIX)

**SYNOPSIS**

```
int timer_create
(
 clockid_t clock_id, /* clock ID (always CLOCK_REALTIME) */
 struct sigevent * evp, /* user event handler */
 timer_t * pTimer /* ptr to return value */
)
```

**DESCRIPTION** This routine returns a value in *pTimer* that identifies the timer in subsequent timer requests. The *evp* argument, if non-NULL, points to a **sigevent** structure, which is allocated by the application and defines the signal number and application-specific data to be sent to the task when the timer expires. If *evp* is NULL, a default signal (SIGALRM) is queued to the task, and the signal data is set to the timer ID. Initially, the timer is disarmed.

**RETURNS** 0 (OK), or -1 (ERROR) if too many timers already are allocated or the signal number is invalid.

**ERRNO** EMTIMERS, EINVAL, ENOSYS, EAGAIN, S\_memLib\_NOT\_ENOUGH\_MEMORY

**SEE ALSO** **timerLib**, *timer\_delete()*

---

## *timer\_delete()*

**NAME** *timer\_delete()* – remove a previously created timer (POSIX)

**SYNOPSIS**

```
int timer_delete
(
 timer_t timerid /* timer ID */
)
```

**DESCRIPTION** This routine removes a timer.

**RETURNS** 0 (OK), or -1 (ERROR) if *timerid* is invalid.

**ERRNO** EINVAL

**SEE ALSO** *timerLib*, *timer\_create()*

---

## *timer\_getoverrun()*

**NAME** *timer\_getoverrun()* – return the timer expiration overrun (POSIX)

**SYNOPSIS**

```
int timer_getoverrun
(
 timer_t timerid /* timer ID */
)
```

**DESCRIPTION** This routine returns the timer expiration overrun count for *timerid*, when called from a timer expiration signal catcher. The overrun count is the number of extra timer expirations that have occurred, up to the implementation-defined maximum `_POSIX_DELAYTIMER_MAX`. If the count is greater than the maximum, it returns the maximum.

**RETURNS** The number of overruns, or `_POSIX_DELAYTIMER_MAX` if the count equals or is greater than `_POSIX_DELAYTIMER_MAX`, or -1 (ERROR) if *timerid* is invalid.

**ERRNO** EINVAL, ENOSYS

**SEE ALSO** *timerLib*

**timer\_gettime()**

---

**timer\_gettime()**

**NAME** *timer\_gettime()* – get the remaining time before expiration and the reload value (POSIX)

**SYNOPSIS**

```
int timer_gettime
(
 timer_t timerid, /* timer ID */
 struct itimerspec * value /* where to return remaining time */
)
```

**DESCRIPTION** This routine gets the remaining time and reload value of a specified timer. Both values are copied to the *value* structure.

**RETURNS** 0 (OK), or -1 (ERROR) if *timerid* is invalid.

**ERRNO** EINVAL

**SEE ALSO** timerLib

---

**timer\_settime()**

**NAME** *timer\_settime()* – set the time until the next expiration and arm timer (POSIX)

**SYNOPSIS**

```
int timer_settime
(
 timer_t timerid, /* timer ID */
 int flags, /* absolute or relative */
 const struct itimerspec * value, /* time to be set */
 struct itimerspec * ovalue /* previous time set (NULL=no result) */
)
```

**DESCRIPTION** This routine sets the next expiration of the timer, using the *.it\_value* of *value*, thus arming the timer. If the timer is already armed, this call resets the time until the next expiration. If *.it\_value* is zero, the timer is disarmed.

If *flags* is not equal to **TIMER\_ABSTIME**, the interval is relative to the current time, the expiration is set to the difference between the absolute time of *.it\_value* and the current value of the clock associated with *timerid*. If the time has already passed, then the timer expiration notification is made immediately. The task that sets the timer receives the

signal; in other words, the `taskId` is noted. If a timer is set by an ISR, the signal is delivered to the task that created the timer.

The reload value of the timer is set to the value specified by the `.it_interval` field of `value`. When a timer is armed with a nonzero `.it_interval` a periodic timer is set up.

Time values that are between two consecutive non-negative integer multiples of the resolution of the specified timer are rounded up to the larger multiple of the resolution.

If `ovalue` is non-NULL, the routine stores a value representing the previous amount of time before the timer would have expired. Or if the timer is disarmed, the routine stores zero, together with the previous timer reload value. The `ovalue` parameter is the same value as that returned by `timer_gettime()` and is subject to the timer resolution.

**WARNING** If `clock_settime()` is called to reset the absolute clock time after a timer has been set with `timer_settime()`, and if `flags` is equal to `TIMER_ABSTIME`, then the timer will behave unpredictably. If you must reset the absolute clock time after setting a timer, do not use `flags` equal to `TIMER_ABSTIME`.

**RETURNS** 0 (OK), or -1 (ERROR) if `timerid` is invalid, the number of nanoseconds specified by `value` is less than 0 or greater than or equal to 1,000,000,000, or the time specified by `value` exceeds the maximum allowed by the timer.

**ERRNO** EINVAL

**SEE ALSO** `timerLib`

---

## *timex()*

**NAME** `timex()` – time a single execution of a function or functions

**SYNOPSIS**

```
void timex
(
 FUNCPTR func, /* function to time (optional) */
 int arg1, /* first of up to 8 args to call func with (optional) */
 int arg2,
 int arg3,
 int arg4,
 int arg5,
 int arg6,
 int arg7,
 int arg8
)
```

***timexClear()***

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | This routine times a single execution of a specified function with up to eight of the function's arguments. If no function is specified, it times the execution of the current list of functions to be timed, which is created using <i>timexFunc()</i> , <i>timexPre()</i> , and <i>timexPost()</i> . If <i>timex()</i> is executed with a function argument, the entire current list is replaced with the single specified function.<br><br>When execution is complete, <i>timex()</i> displays the execution time. If the execution was so fast relative to the clock rate that the time is meaningless (error > 50%), a warning message is printed instead. In such cases, use <i>timexN()</i> . |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                 |                                                                                                                                                                                                                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>     | <i>timexFunc()</i> – specify functions to be timed                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b> | <pre>void timexFunc (     int    i,      /* function number in list (0..3) */     FUNCPTR func, /* function to be added (NULL if to be deleted) */     int    arg1, /* first of up to 8 args to call function with */     int    arg2,     int    arg3,     int    arg4,     int    arg5,     int    arg6,</pre> |

```

int arg7,
int arg8
)

```

- DESCRIPTION** This routine adds or deletes functions in the list of functions to be timed as a group by calls to *timex()* or *timexN()*. Up to four functions can be included in the list. The argument *i* specifies the function's position in the sequence of execution (0, 1, 2, or 3). A function is deleted by specifying its sequence number *i* and NULL for the function argument *func*.
- RETURNS** N/A
- SEE ALSO** *timexLib*, *timex()*, *timexN()*

---

## *timexHelp()*

- NAME** *timexHelp()* – display synopsis of execution timer facilities
- SYNOPSIS** `void timexHelp (void)`
- DESCRIPTION** This routine displays the following summary of the available execution timer functions:
- |                         |                               |                                               |
|-------------------------|-------------------------------|-----------------------------------------------|
| <code>timexHelp</code>  |                               | Print this list.                              |
| <code>timex</code>      | <code>[func,[args...]]</code> | Time a single execution.                      |
| <code>timexN</code>     | <code>[func,[args...]]</code> | Time repeated executions.                     |
| <code>timexClear</code> |                               | Clear all functions.                          |
| <code>timexFunc</code>  | <code>i,func,[args...]</code> | Add timed function number <i>i</i> (0,1,2,3). |
| <code>timexPre</code>   | <code>i,func,[args...]</code> | Add pre-timing function number <i>i</i> .     |
| <code>timexPost</code>  | <code>i,func,[args...]</code> | Add post-timing function number <i>i</i> .    |
| <code>timexShow</code>  |                               | Show all functions to be called.              |
- Notes:
- 1) `timexN()` will repeat calls enough times to get timing accuracy to approximately 2%.
  - 2) A single function can be specified with `timex()` and `timexN()`; or, multiple functions can be pre-set with `timexFunc()`.
  - 3) Up to 4 functions can be pre-set with `timexFunc()`, `timexPre()`, and `timexPost()`, i.e., *i* in the range 0 - 3.
  - 4) `timexPre()` and `timexPost()` allow locking/unlocking, or raising/lowering priority before/after timing.
- RETURNS** N/A
- SEE ALSO** *timexLib*

## *timexInit()*

|                    |                                                                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>timexInit()</i> – include the execution timer library                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <code>void timexInit (void)</code>                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | This null routine is provided so that <b>timexLib</b> can be linked into the system. If the configuration macro <b>INCLUDE_TIMEX</b> is defined, it is called by the root task, <i>usrRoot()</i> , in <i>usrConfig.c</i> . |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                        |
| <b>SEE ALSO</b>    | <b>timexLib</b>                                                                                                                                                                                                            |

## *timexN()*

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>timexN()</i> – time repeated executions of a function or group of functions                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <pre>void timexN (     FUNCPTR func, /* function to time (optional) */     int     arg1, /* first of up to 8 args to call function with */     int     arg2,     int     arg3,     int     arg4,     int     arg5,     int     arg6,     int     arg7,     int     arg8 )</pre>                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | This routine times the execution of the current list of functions to be timed in the same manner as <i>timex()</i> ; however, the list of functions is called a variable number of times until sufficient resolution is achieved to establish the time with an error less than 2%. (Since each iteration of the list may be measured to a resolution of +/- 1 clock tick, repetitive timings decrease this error to 1/N ticks, where N is the number of repetitions.) |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SEE ALSO</b>    | <b>timexLib</b> , <i>timexFunc()</i> , <i>timex()</i>                                                                                                                                                                                                                                                                                                                                                                                                                 |

## *timexPost()*

**NAME** *timexPost()* – specify functions to be called after timing

**SYNOPSIS**

```
void timexPost
(
 int i, /* function number in list (0..3) */
 FUNCPTR func, /* function to be added (NULL if to be deleted) */
 int arg1, /* first of up to 8 args to call function with */
 int arg2,
 int arg3,
 int arg4,
 int arg5,
 int arg6,
 int arg7,
 int arg8
)
```

**DESCRIPTION** This routine adds or deletes functions in the list of functions to be called immediately following the timed functions. A maximum of four functions may be included. Up to eight arguments may be passed to each function.

**RETURNS** N/A

**SEE ALSO** *timexLib*

---

## *timexPre()*

**NAME** *timexPre()* – specify functions to be called prior to timing

**SYNOPSIS**

```
void timexPre
(
 int i, /* function number in list (0..3) */
 FUNCPTR func, /* function to be added (NULL if to be deleted) */
 int arg1, /* first of up to 8 args to call function with */
 int arg2,
 int arg3,
 int arg4,
 int arg5,
 int arg6,
```

***timexShow()***

```

 int arg7,
 int arg8
)

```

| <b>DESCRIPTION</b>   | <p>This routine generates a string that is a valid file name and not the same as the name of an existing file. It generates a different string each time it is called, up to <code>TMP_MAX</code> times.</p> <p>If the argument is a null pointer, <i>tmpnam()</i> leaves its result in an internal static object and returns a pointer to that object. Subsequent calls to <i>tmpnam()</i> may modify the same object. If the argument is not a null pointer, it is assumed to point to an array of at least <code>L_tmpnam</code> chars; <i>tmpnam()</i> writes its result in that array and returns the argument as its value.</p> |
| <b>INCLUDE FILES</b> | <code>stdio.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>RETURNS</b>       | A pointer to the file name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## *truncf()*

|                      |                                                                                  |
|----------------------|----------------------------------------------------------------------------------|
| <b>NAME</b>          | <i>truncf()</i> – truncate to integer                                            |
| <b>SYNOPSIS</b>      | <pre>float truncf (     float x /* value to truncate */ )</pre>                  |
| <b>DESCRIPTION</b>   | This routine discards the fractional part of a single-precision value <i>x</i> . |
| <b>INCLUDE FILES</b> | <b>math.h</b>                                                                    |
| <b>RETURNS</b>       | The integer portion of <i>x</i> , represented in single precision.               |
| <b>SEE ALSO</b>      | <b>mathALib</b>                                                                  |

**ts()**

---

**ts()**

**NAME** *ts()* – suspend a task

**SYNOPSIS**

```
void ts
(
 int taskNameOrId /* task name or task ID */
)
```

**DESCRIPTION** This command suspends the execution of a specified task. It simply calls *taskSuspend()*.

**RETURNS** N/A

**SEE ALSO** *usrLib*, *tr()*, *taskSuspend()*, *VxWorks Programmer's Guide: Target Shell*, **windsh**, *Tornado User's Guide: Shell*

---

**tsp()**

**NAME** *tsp()* – return the contents of register **sp** (i960)

**SYNOPSIS**

```
int tsp
(
 int taskId /* task ID, 0 means default task */
)
```

**DESCRIPTION** This command extracts the contents of register **sp**, the stack pointer, from the TCB of a specified task. If *taskId* is omitted or 0, the current default task is assumed.

Note: The name *tsp()* is used because *sp()* (the logical name choice) conflicts with the routine *sp()* for spawning a task with default parameters.

**RETURNS** The contents of the **sp** register.

**SEE ALSO** *dbgArchLib*, *VxWorks Programmer's Guide: Target Shell*

---

**tt()**

**NAME** `tt()` – display a stack trace of a task

**SYNOPSIS**

```
STATUS tt
(
 int taskNameOrId /* task name or task ID */
)
```

**DESCRIPTION** This routine displays a list of the nested routine calls that the specified task is in. Each routine call and its parameters are shown.

If *taskNameOrId* is not specified or zero, the last task referenced is assumed. The *tt()* routine can only trace the stack of a task other than itself. For instance, when *tt()* is called from the shell, it cannot trace the shell's stack.

**EXAMPLE**

```
-> tt "logTask"
3ab92 _vxTaskEntry +10 : _logTask (0, 0, 0, 0, 0, 0, 0, 0, 0, 0)
ee6e _logTask +12 : _read (5, 3f8a10, 20)
d460 _read +10 : _iosRead (5, 3f8a10, 20)
e234 _iosRead +9c : _pipeRead (3f8a10, 20)
23978 _pipeRead +24 : _semTake (3f8b78)
value = 0 = 0x0
```

This indicates that *logTask()* is currently in *semTake()* (with one parameter) and was called by *pipeRead()* (with three parameters), which was called by *iosRead()* (with three parameters), and so on.

**CAVEAT** In order to do the trace, some assumptions are made. In general, the trace will work for all C language routines and for assembly language routines that start with a LINK instruction. Some C compilers require specific flags to generate the LINK first. Most VxWorks assembly language routines include LINK instructions for this reason. The trace facility may produce inaccurate results or fail completely if the routine is written in a language other than C, the routine's entry point is non-standard, or the task's stack is corrupted. Also, all parameters are assumed to be 32-bit quantities, so structures passed as parameters will be displayed as *long* integers.

**RETURNS** OK, or ERROR if the task does not exist.

**SEE ALSO** *dbgLib*, *VxWorks Programmer's Guide: Target Shell*, *windsh*, *Tornado User's Guide: Shell*

## *ttyDevCreate()*

**NAME** *ttyDevCreate()* – create a VxWorks device for a serial channel

**SYNOPSIS**

```
STATUS ttyDevCreate
(
 char * name, /* name to use for this device */
 SIO_CHAN * pSioChan, /* pointer to core driver structure */
 int rdBufSize, /* read buffer size, in bytes */
 int wrtBufSize /* write buffer size, in bytes */
)
```

**DESCRIPTION** This routine creates a device on a specified serial channel. Each channel to be used should have exactly one device associated with it by calling this routine.

For instance, to create the device `"/tyCo/0"`, with buffer sizes of 512 bytes, the proper call would be:

```
 ttyDevCreate ("/tyCo/0", pSioChan, 512, 512);
```

Where `pSioChan` is the address of the underlying `SIO_CHAN` serial channel descriptor (defined in `sioLib.h`). This routine is typically called by `usrRoot()` in `usrConfig.c`

**RETURNS** OK, or ERROR if the driver is not installed, or the device already exists.

**SEE ALSO** `ttyDrv`

---

## *ttyDrv()*

**NAME** *ttyDrv()* – initialize the tty driver

**SYNOPSIS** `STATUS ttyDrv (void)`

**DESCRIPTION** This routine initializes the tty driver, which is the OS interface to core serial channel(s). Normally, it is called by `usrRoot()` in `usrConfig.c`.

After this routine is called, `ttyDevCreate()` is typically called to bind serial channels to VxWorks devices.

**RETURNS** OK, or ERROR if the driver cannot be installed.

**SEE ALSO** `ttyDrv`

---

## *tyAbortFuncSet()*

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>tyAbortFuncSet()</i> – set the abort function                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <pre>void tyAbortFuncSet (     FUNCPTR func /* routine to call when abort char received */ )</pre>                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | <p>This routine sets the function that will be called when the abort character is received on a tty. There is only one global abort function, used for any tty on which <b>OPT_ABORT</b> is enabled. When the abort character is received from a tty with <b>OPT_ABORT</b> set, the function specified in <i>func</i> will be called, with no parameters, from interrupt level.</p> <p>Setting an abort function of NULL will disable the abort function.</p> |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SEE ALSO</b>    | <i>tyLib</i> , <i>tyAbortSet()</i>                                                                                                                                                                                                                                                                                                                                                                                                                            |

---

## *tyAbortSet()*

|                    |                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>tyAbortSet()</i> – change the abort character                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <pre>void tyAbortSet (     char ch /* char to be abort */ )</pre>                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>This routine sets the abort character to <i>ch</i>. The default abort character is CTRL+C.</p> <p>Typing the abort character to any device whose <b>OPT_ABORT</b> option is set will cause the shell task to be killed and restarted. Note that the character set by this routine applies to all devices whose handlers use the standard tty package <b>tyLib</b>.</p> |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SEE ALSO</b>    | <i>tyLib</i> , <i>tyAbortFuncSet()</i>                                                                                                                                                                                                                                                                                                                                    |

---

## *tyBackspaceSet()*

**NAME** *tyBackspaceSet()* – change the backspace character

**SYNOPSIS**

```
void tyBackspaceSet
(
 char ch /* char to be backspace */
)
```

**DESCRIPTION** This routine sets the backspace character to *ch*. The default backspace character is CTRL+H.

Typing the backspace character to any device operating in line protocol mode (**OPT\_LINE** set) will cause the previous character typed to be deleted, up to the beginning of the current line. Note that the character set by this routine applies to all devices whose handlers use the standard tty package **tyLib**.

**RETURNS** N/A

**SEE ALSO** **tyLib**

---

## *tyDeleteLineSet()*

**NAME** *tyDeleteLineSet()* – change the line-delete character

**SYNOPSIS**

```
void tyDeleteLineSet
(
 char ch /* char to be line-delete */
)
```

**DESCRIPTION** This routine sets the line-delete character to *ch*. The default line-delete character is CTRL+U.

Typing the delete character to any device operating in line protocol mode (**OPT\_LINE** set) will cause all characters in the current line to be deleted. Note that the character set by this routine applies to all devices whose handlers use the standard tty package **tyLib**.

**RETURNS** N/A

**SEE ALSO** **tyLib**

---

## *tyDevInit()*

**NAME** *tyDevInit()* – initialize the tty device descriptor

**SYNOPSIS**

```
STATUS tyDevInit
(
 TY_DEV_ID pTyDev, /* ptr to tty dev descriptor to init */
 int rdBufSize, /* size of read buffer in bytes */
 int wrtBufSize, /* size of write buffer in bytes */
 FUNCPTR txStartup /* device transmit start-up routine */
)
```

**DESCRIPTION** This routine initializes a tty device descriptor according to the specified parameters. The initialization includes allocating read and write buffers of the specified sizes from the memory pool, and initializing their respective buffer descriptors. The semaphores are initialized and the write semaphore is given to enable writers. Also, the transmitter start-up routine pointer is set to the specified routine. All other fields in the descriptor are zeroed.

This routine should be called only by serial drivers.

**RETURNS** OK, or ERROR if there is not enough memory to allocate data structures.

**SEE ALSO** *tyLib*

---

## *tyEOFSet()*

**NAME** *tyEOFSet()* – change the end-of-file character

**SYNOPSIS**

```
void tyEOFSet
(
 char ch /* char to be EOF */
)
```

**DESCRIPTION** This routine sets the EOF character to *ch*. The default EOF character is CTRL-D.

Typing the EOF character to any device operating in line protocol mode (*OPT\_LINE* set) will cause no character to be entered in the current line, but will cause the current line to be terminated (thus without a newline character). The line is made available to reading tasks. Thus, if the EOF character is the first character input on a line, a line length of zero characters is returned to the reader. This is the standard end-of-file indication on a read

***tyIoctl()***

call. Note that the EOF character set by this routine will apply to all devices whose handlers use the standard tty package **tyLib**.

**RETURNS** N/A

**SEE ALSO** **tyLib**

***tyIoctl()***

**NAME** *tyIoctl()* – handle device control requests

**SYNOPSIS**

```
STATUS tyIoctl
(
 TY_DEV_ID pTyDev, /* ptr to device to control */
 int request, /* request code */
 int arg /* some argument */
)
```

**DESCRIPTION** This routine handles *ioctl()* requests for tty devices. The I/O control functions for tty devices are described in the manual entry for **tyLib**.

**BUGS** In line protocol mode (**OPT\_LINE** option set), the **FIONREAD** function actually returns the number of characters available plus the number of lines in the buffer. Thus, if five lines consisting of just **NEWLINES** were in the input buffer, the **FIONREAD** function would return the value ten (five characters + five lines).

**RETURNS** OK or ERROR.

**SEE ALSO** **tyLib**

***tyIRd()***

**NAME** *tyIRd()* – interrupt-level input

**SYNOPSIS**

```
STATUS tyIRd
(
 TY_DEV_ID pTyDev, /* ptr to tty device descriptor */
 char inchar /* character read */
)
```

**DESCRIPTION** This routine handles interrupt-level character input for tty devices. A device driver calls this routine when it has received a character. This routine adds the character to the ring buffer for the specified device, and gives a semaphore if a task is waiting for it.

This routine also handles all the special characters, as specified in the option word for the device, such as X-on, X-off, NEWLINE, or backspace.

**RETURNS** OK, or ERROR if the ring buffer is full.

**SEE ALSO** **tyLib**

---

## ***tyITx()***

**NAME** *tyITx()* – interrupt-level output

**SYNOPSIS**

```
STATUS tyITx
(
 TY_DEV_ID pTyDev, /* pointer to tty device descriptor */
 char * pChar /* where to put character to be output */
)
```

**DESCRIPTION** This routine gets a single character to be output to a device. It looks at the ring buffer for *pTyDev* and gives the caller the next available character, if there is one. The character to be output is copied to *pChar*.

**RETURNS** OK if there are more characters to send, or ERROR if there are no more characters.

**SEE ALSO** **tyLib**

---

## ***tyMonitorTrapSet()***

**NAME** *tyMonitorTrapSet()* – change the trap-to-monitor character

**SYNOPSIS**

```
void tyMonitorTrapSet
(
 char ch /* char to be monitor trap */
)
```

***tyRead()***

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | <p>This routine sets the trap-to-monitor character to <i>ch</i>. The default trap-to-monitor character is CTRL+X.</p> <p>Typing the trap-to-monitor character to any device whose <b>OPT_MON_TRAP</b> option is set will cause the resident ROM monitor to be entered, if one is present. Once the ROM monitor is entered, the normal multitasking system is halted.</p> <p>Note that the trap-to-monitor character set by this routine will apply to all devices whose handlers use the standard tty package <b>tyLib</b>. Also note that not all systems have a monitor trap available.</p> |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SEE ALSO</b>    | <b>tyLib</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>ulipDebugSet()</i> – Set debug flag in UNIX's ULIP driver                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <pre>STATUS ulipDebugSet (     int debugFlag )</pre>                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | This function uses an ioctl call to UNIX's (Solaris's) ULIP driver to set that driver's debugging flag to the value in debugFlag. Because there is no simple way for the caller to ascertain the unit number of the interface in use, all unit numbers are looped over and each receives the ioctl. Possible values for the debug flag are discussed above in this file, although all the levels have not been implemented. |

This is not the right place to put this function (user callable routines would be more appropriately placed in **simLib.h**). Because of the requirement to use both Sun structures (to bundle ioctl data) and VxWorks structures (**ul\_softc**), and given the same requirements when calling the **FIOSETUSED** ioctl, this seems the best place to put it.

**RETURNS** OK or ERROR if the ioctl fails

## *ulipDelete()*

**NAME** *ulipDelete()* – delete a ULIP interface (VxSim)

**SYNOPSIS**

```
STATUS ulipDelete
(
 int unit /* ULIP unit number */
)
```

**DESCRIPTION** This routine detaches the ULIP unit and frees up system resources taken up by this ULIP interface.

**RETURNS** OK, or ERROR if the unit number is invalid or the interface is uninitialized.

**ERRNO** **S\_if\_ul\_INVALID\_UNIT\_NUMBER**, **S\_if\_ul\_UNIT\_UNINITIALIZED**

**SEE ALSO** **if\_ulip**, *VxSim User's Guide*

## *ultraLoad()*

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>ultraLoad()</i> – initialize the driver and device                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <pre>END_OBJ* ultraLoad (     char * initString /* String to be parsed by the driver. */ )</pre>                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p>This routine initializes the driver and the device to the operational state. All of the device-specific parameters are passed in <i>initString</i>, which expects a string of the following format:</p> <pre>unit:ioAddr:memAddr:vecNum:intLvl:config:offset"</pre> <p>This routine can be called in two modes. If it is called with an empty but allocated string, it places the name of this device (that is, "ultra") into the <i>initString</i> and returns 0.</p> |

***ultraMemInit()***

If the string is allocated and not empty, the routine attempts to load the driver using the values specified in the string.

**RETURNS** An END object pointer, or NULL on error, or 0 and the name of the device if the *initString* was NULL.

**SEE ALSO** **ultraEnd**

***ultraMemInit()***

**NAME** *ultraMemInit()* – initialize memory for the chip

**SYNOPSIS**

```
STATUS ultraMemInit
(
 ULTRA_DEVICE * pDrvCtrl, /* device to be initialized */
 int clNum /* number of clusters to allocate */
)
```

**DESCRIPTION** Using data in the control structure, setup and initialize the memory areas needed. If the memory address is not already specified, then allocate cache safe memory.

**RETURNS** OK or ERROR.

**SEE ALSO** **ultraEnd**

***ultraParse()***

**NAME** *ultraParse()* – parse the init string

**SYNOPSIS**

```
STATUS ultraParse
(
 ULTRA_DEVICE * pDrvCtrl, /* device pointer */
 char * initString /* information string */
)
```

**DESCRIPTION** Parse the input string. Fill in values in the driver control structure. The initialization string format is: *unit:ioAddr:memAddr:vecNum:intLvl:config:offset*

*unit*  
Device unit number, a small integer.

*ioAddr*  
I/O address

*memAddr*  
Memory address, assumed to be 16k bytes in length.

*vecNum*  
Interrupt vector number (used with *sysIntConnect()*).

*intLvl*  
Interrupt level.

*config*  
Ultra config (0: RJ45 + AUI(Thick) 1: RJ45 + BNC(Thin)).

*offset*  
Memory offset for alignment.

**RETURNS** OK, or ERROR if any arguments are invalid.

**SEE ALSO** **ultraEnd**

---

## ***ultraPut()***

**NAME** *ultraPut()* – copy a packet to the interface.

**SYNOPSIS**

```
#ifdef BSD43_DRIVER LOCAL void ultraPut
(
 int unit /* device unit number */
)
```

**DESCRIPTION** Copy from mbuf chain to transmitter buffer in shared memory.

**RETURNS** N/A

**SEE ALSO** **if\_ultra**

**ultraShow()**

---

**ultraShow()****NAME** *ultraShow()* – display statistics for the **ultra** network interface**SYNOPSIS**  

```
void ultraShow
(
 int unit, /* interface unit */
 BOOL zap /* zero totals */
)
```

**DESCRIPTION** This routine displays statistics about the **elc** Ethernet network interface. It has two parameters:

*unit*  
 interface unit; should be 0.

*zap*  
 if 1, all collected statistics are cleared to zero.

**RETURNS** N/A**SEE ALSO** **if\_ultra**

---

**ungetc()****NAME** *ungetc()* – push a character back into an input stream (ANSI)**SYNOPSIS**  

```
int ungetc
(
 int c, /* character to push */
 FILE * fp /* input stream */
)
```

**DESCRIPTION** This routine pushes a character *c* (converted to an **unsigned char**) back into the specified input stream. The pushed-back characters will be returned by subsequent reads on that stream in the reverse order of their pushing. A successful intervening call on the stream to a file positioning function (*fseek()*, *fsetpos()*, or *rewind()*) discards any pushed-back characters for the stream. The external storage corresponding to the stream is unchanged.

One character of push-back is guaranteed. If *ungetc()* is called too many times on the same stream without an intervening read or file positioning operation, the operation may fail.

If the value of *c* equals EOF, the operation fails and the input stream is unchanged.

A successful call to *ungetc()* clears the end-of-file indicator for the stream. The value of the file position indicator for the stream after reading or discarding all pushed-back characters is the same as it was before the character were pushed back. For a text stream, the value of its file position indicator after a successful call to *ungetc()* is unspecified until all pushed-back characters are read or discarded. For a binary stream, the file position indicator is decremented by each successful call to *ungetc()*; if its value was zero before a call, it is indeterminate after the call.

**INCLUDE** `stdio.h`

**RETURNS** The pushed-back character after conversion, or EOF if the operation fails.

**SEE ALSO** `ansiStdio`, `getc()`, `fgetc()`

---

## *unixDevInit()*

**NAME** *unixDevInit()* – initialize a UNIX\_DUSART

**SYNOPSIS**

```
void unixDevInit
(
 UNIX_CHAN * pChan
)
```

**DESCRIPTION** This routine initializes the driver function pointers and then resets to a quiescent state. The BSP must have already opened all the file descriptors in the structure before passing it to this routine.

**RETURNS** N/A

**SEE ALSO** `unixSio`

## **unixDevInit2()**

**NAME** *unixDevInit2()* – enable interrupts

**SYNOPSIS**

```
void unixDevInit2
(
 UNIX_CHAN * pChan
)
```

**RETURNS** N/A

**SEE ALSO** *unixSio*

---

## **unixDiskDevCreate()**

**NAME** *unixDiskDevCreate()* – create a UNIX disk device

**SYNOPSIS**

```
BLK_DEV *unixDiskDevCreate
(
 char * unixFile, /* name of the UNIX file */
 int bytesPerBlk, /* number of bytes per block */
 int blksPerTrack, /* number of blocks per track */
 int nBlocks /* number of blocks on this device */
)
```

**DESCRIPTION** This routine creates a UNIX disk device.

The *unixFile* parameter specifies the name of the UNIX file to use for the disk device.

The *bytesPerBlk* parameter specifies the size of each logical block on the disk. If *bytesPerBlk* is zero, 512 is the default.

The *blksPerTrack* parameter specifies the number of blocks on each logical track of the disk. If *blksPerTrack* is zero, the count of blocks per track is set to *nBlocks* (i.e., the disk is defined as having only one track).

The *nBlocks* parameter specifies the size of the disk, in blocks. If *nBlocks* is zero, a default size is used. The default is calculated as the size of the UNIX disk divided by the number of bytes per block.

This routine is only applicable to VxSim for Solaris and VxSim for HP.

**RETURNS** A pointer to block device (BLK\_DEV) structure, or NULL, if unable to open the UNIX disk.

SEE ALSO *unixDrv*

---

## *unixDiskInit()*

**NAME** *unixDiskInit()* – initialize a dosFs disk on top of UNIX

**SYNOPSIS**

```
void unixDiskInit
(
 char * unixFile, /* UNIX file name */
 char * volName, /* dosFs name */
 int diskSize /* number of bytes */
)
```

**DESCRIPTION** This routine provides some convenience for a user wanting to create a UNIX disk-based dosFs file system under VxWorks. The user only specifies the UNIX file to use, the dosFs volume name, and the size of the volume in bytes, if the UNIX file needs to be created.

This routine is only applicable to VxSim for Solaris and VxSim for HP.

**RETURNS** N/A

SEE ALSO *unixDrv*

---

## *unixDrv()*

**NAME** *unixDrv()* – install UNIX disk driver

**SYNOPSIS** `STATUS unixDrv (void)`

**DESCRIPTION** Used in `usrConfig.c` to cause the UNIX disk driver to be linked in when building VxWorks. Otherwise, it is not necessary to call this routine before using the UNIX disk driver.

This routine is only applicable to VxSim for Solaris and VxSim for HP.

**RETURNS** OK (always).

SEE ALSO *unixDrv*

**unixIntRcv()**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>unld()</i> – unload an object module by specifying a file name or module ID                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <pre>STATUS unld (     void * nameOrId, /* name or ID of the object module file */     int options )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>This routine unloads the specified object module from the system. The module can be specified by name or by module ID. For a.out and ECOFF format modules, unloading does the following:</p> <ol style="list-style-type: none"> <li>(1) It frees the space allocated for text, data, and BSS segments, unless <i>loadModuleAt()</i> was called with specific addresses, in which case the user is responsible for freeing the space.</li> <li>(2) It removes all symbols associated with the object module from the system symbol table.</li> <li>(3) It removes the module descriptor from the module list.</li> </ol> <p>For other modules of other formats, unloading has similar effects.</p> <p>Before any modules are unloaded, all breakpoints in the system are deleted. If you need to keep breakpoints, set the options parameter to <b>UNLD_KEEP_BREAKPOINTS</b>. No breakpoints can be set in code that is unloaded.</p> |
| <b>RETURNS</b>     | OK or ERROR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## *unldByGroup()*

**NAME** *unldByGroup()* – unload an object module by specifying a group number

**SYNOPSIS**

```
STATUS unldByGroup
(
 UINT16 group, /* group number to unload */
 int options /* options, currently unused */
)
```

**DESCRIPTION** This routine unloads an object module that has a group number matching *group*. See the manual entries for *unld()* or *unldLib* for more information on module unloading.

**RETURNS** OK or ERROR.

**SEE ALSO** *unldLib*, *unld()*

---

## *unldByModuleId()*

**NAME** *unldByModuleId()* – unload an object module by specifying a module ID

**SYNOPSIS**

```
STATUS unldByModuleId
(
 MODULE_ID moduleId, /* module ID to unload */
 int options
)
```

**DESCRIPTION** This routine unloads an object module that has a module ID matching *moduleId*. See the manual entries for *unld()* or *unldLib* for more information on module unloading.

**RETURNS** OK or ERROR.

**SEE ALSO** *unldLib*, *unld()*

---

## ***unldByNameAndPath()***

**NAME** *unldByNameAndPath()* – unload an object module by specifying a name and path

**SYNOPSIS**

```
STATUS unldByNameAndPath
(
 char * name, /* name of the object module to unload */
 char * path, /* path to the object module to unload */
 int options /* options, currently unused */
)
```

**DESCRIPTION** This routine unloads an object module specified by *name* and *path*. See the manual entries for *unld()* or **unldLib** for more information on module unloading.

**RETURNS** OK or ERROR.

**SEE ALSO** **unldLib**, *unld()*

---

## ***unlink()***

**NAME** *unlink()* – delete a file (POSIX)

**SYNOPSIS**

```
STATUS unlink
(
 char * name /* name of the file to remove */
)
```

**DESCRIPTION** This routine deletes a specified file. It performs the same function as *remove()* and is provided for POSIX compatibility.

**RETURNS** OK if there is no delete routine for the device or the driver returns OK; ERROR if there is no such device or the driver returns ERROR.

**SEE ALSO** **ioLib**, *remove()*

---

## *usrAtaConfig()*

- NAME** *usrAtaConfig()* – mount a DOS file system from an ATA hard disk
- SYNOPSIS**
- ```
STATUS usrAtaConfig
(
    int    ctrl,    /* 0: primary address, 1: secondary address */
    int    drive,  /* drive number of hard disk (0 or 1) */
    char * fileName /* mount point */
)
```
- DESCRIPTION** This routine mounts a DOS file system from an ATA hard disk. Parameters:
- drive*
the drive number of the hard disk; 0 is **C:** and 1 is **D:**.
- fileName*
the mount point, for example, */ata0/*.
- NOTE** Because VxWorks does not support partitioning, hard disks formatted and initialized on VxWorks are not compatible with DOS machines. This routine does not refuse to mount a hard disk that was initialized on VxWorks. The hard disk is assumed to have only one partition with a partition record in sector 0.
- RETURNS** OK or ERROR.
- SEE ALSO** *src/config/usrAta.c*, *VxWorks Programmer's Guide: I/O System, Local File Systems, Intel i386/i486/Pentium*

usrAtaPartition()

- NAME** *usrAtaPartition()* – get an offset to the first partition of the drive
- SYNOPSIS**
- ```
int usrAtaPartition
(
 int ctrl, /* 0: primary address, 1: secondary address */
 int drive, /* drive number of hard disk (0 or 1) */
 DOS_PART_TBL * pPart /* pointer to the partition table */
)
```

***usrClock()***

|                    |                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | This routine gets an offset to the first partition of the drive. The value of offset is passed to the macro <code>ATA_SWAP</code> for endian adjustment. For the <i>drive</i> parameter, 0 is <b>C:</b> and 1 is <b>D:</b> . |
| <b>RETURNS</b>     | The offset to the partition                                                                                                                                                                                                  |
| <b>SEE ALSO</b>    | <code>usrAta</code>                                                                                                                                                                                                          |

| <b>SYNOPSIS</b>    | <pre>STATUS usrFdConfig (     int    drive, /* drive number of floppy disk (0 - 3) */     int    type,  /* type of floppy disk */     char * fileName /* mount point */ ) </pre> |
| <b>DESCRIPTION</b> | <p>This routine mounts a DOS file system from a floppy disk device.</p> <p>The <i>drive</i> parameter is the drive number of the floppy disk; valid values are 0 to 3.</p>       |

The *type* parameter specifies the type of diskette, which is described in the structure table **fdTypes[]** in **sysLib.c**. *type* is an index to the table. Currently the table contains two diskette types:

- A *type* of 0 indicates the first entry in the table (3.5" 2HD, 1.44MB);
- A *type* of 1 indicates the second entry in the table (5.25" 2HD, 1.2MB).

The *fileName* parameter is the mount point, e.g., */fd0/*.

|                 |                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NOTE</b>     | Do not attempt to unmount a volume that was mounted with <i>usrFdConfig()</i> using <i>dosFsVolUnmount()</i> . <i>usrFdConfig()</i> does not return the <b>DOS_VOL_CONFIG</b> structure required by <i>dosFsVolUnmount()</i> . Instead use <i>ioctl()</i> with <b>FIOUNMOUNT</b> which accesses the volume information via the file descriptor. |
| <b>RETURNS</b>  | OK or ERROR.                                                                                                                                                                                                                                                                                                                                    |
| <b>SEE ALSO</b> | <b>usrFd</b> , <i>VxWorks Programmer's Guide: I/O System, Local File Systems, Intel i386/i486 Appendix</i>                                                                                                                                                                                                                                      |

| <b>NAME</b>        | <i>usrInit()</i> – user-defined system initialization routine                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <pre>void usrInit (     int startType )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>This is the first C code executed after the system boots. This routine is called by the assembly language start-up routine <i>sysInit()</i> which is in the <b>sysALib</b> module of the target-specific directory. It is called with interrupts locked out. The kernel is not multitasking at this point.</p> <p>This routine starts by clearing BSS; thus all variables are initialized to 0, as per the C specification. It then initializes the hardware by calling <i>sysHwInit()</i>, sets up the interrupt/exception vectors, and starts kernel multitasking with <i>usrRoot()</i> as the root task.</p> |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SEE ALSO</b>    | <b>usrConfig</b> , <b>kernelLib</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>NAME</b>        | <i>usrRoot()</i> – the root task                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <pre>void usrRoot (     char *   pMemPoolStart, /* start of system memory partition */     unsigned memPoolSize   /* initial size of mem pool */ )</pre>                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>This is the first task to run under the multitasking kernel. It performs all final initialization and then starts other tasks.</p> <p>It initializes the I/O system, installs drivers, creates devices, and sets up the network, etc., as necessary for a particular configuration. It may also create and load the system symbol table, if one is to be included. It may then load and spawn additional tasks as needed. In the default configuration, it simply initializes the VxWorks shell.</p> |

**RETURNS** N/A

---

## *usrScsiConfig()*

**NAME** *usrScsiConfig()* – configure SCSI peripherals

**SYNOPSIS** `STATUS usrScsiConfig (void)`

**DESCRIPTION** This code configures the SCSI disks and other peripherals on a SCSI controller chain.

The macro `SCSI_AUTO_CONFIG` will include code to scan all possible device/lun id's and to configure a `scsiPhysDev` structure for each device found. Of course this doesn't include final configuration for disk partitions, floppy configuration parameters, or tape system setup. All of these actions must be performed by user code, either through *sysScsiConfig()*, the startup script, or by the application program.

The user may customize this code on a per BSP basis using the `SYS_SCSI_CONFIG` macro. If defined, then this routine will call the routine *sysScsiConfig()*. That routine is to be provided by the BSP, either in `sysLib.c` or `sysScsi.c`. If `SYS_SCSI_CONFIG` is not defined, then *sysScsiConfig()* will not be called as part of this routine.

An example *sysScsiConfig()* routine can be found in `target/src/config/usrScsi.c`. The example code contains sample configurations for a hard disk, a floppy disk and a tape unit.

**RETURNS** OK or ERROR.

`char * bootString /* boot parameter string */`  
`)`

***uswab()***

- DESCRIPTION** This routine initializes the shared memory objects facility. It sets up the shared memory objects facility if called from processor 0. Then it initializes a shared memory descriptor and calls *smObjAttach()* to attach this CPU to the shared memory object facility.
- When the shared memory pool resides on the local CPU dual ported memory, **SM\_OBJ\_MEM\_ADRS** must be set to **NONE** in **configAll.h** and the shared memory objects pool is allocated from the VxWorks system pool.
- NOTE** The shared memory objects library requires information from fields in the VxWorks boot line. The functions are contained in the **usrNetwork.c** file. If no network services are included, **usrNetwork.c** is not included and the shared memory initialization fails. To avoid this problem, either add **INCLUDE\_NETWORK** to **configAll.h** or extract the bootline cracking routines from **usrNetwork.c** and include them elsewhere.
- RETURNS** OK, or ERROR if unsuccessful.
- SEE ALSO** **usrSmObj**

---

***uswab()***

- NAME** *uswab()* – swap bytes with buffers that are not necessarily aligned
- SYNOPSIS**
- ```
void uswab
(
    char * source,      /* pointer to source buffer */
    char * destination, /* pointer to destination buffer */
    int  nbytes        /* number of bytes to exchange */
)
```
- DESCRIPTION** This routine gets the specified number of bytes from *source*, exchanges the adjacent even and odd bytes, and puts them in *destination*.
- NOTE** Due to speed considerations, this routine should only be used when absolutely necessary. Use *swab()* for aligned swaps.
- It is an error for *nbytes* to be odd.
- RETURNS** N/A
- SEE ALSO** **bLib**, *swab()*

utime()

NAME *utime()* – update time on a file

SYNOPSIS

```
int utime
(
    char *          file,
    struct utimbuf * newTimes
)
```

RETURNS OK or ERROR.

SEE ALSO *dirLib*, *stat()*, *fstat()*, *ls()*

va_arg()

NAME *va_arg()* – expand to an expression having the type and value of the call's next argument

SYNOPSIS

```
void va_arg
(
)
```

DESCRIPTION Each invocation of this macro modifies an object of type **va_list** (*ap*) so that the values of successive arguments are returned in turn. The parameter *type* is a type name specified such that the type of a pointer to an object that has the specified type can be obtained simply by postfixing a * to *type*. If there is no actual next argument, or if *type* is not compatible with the type of the actual next argument (as promoted according to the default argument promotions), the behavior is undefined.

RETURNS The first invocation of *va_arg()* after *va_start()* returns the value of the argument after that specified by *parmN* (the rightmost parameter). Successive invocations return the value of the remaining arguments in succession.

SEE ALSO *ansiStdarg*

va_end()

va_end()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>va_end()</i> – facilitate a normal return from a routine using a va_list object |
| SYNOPSIS | <pre>void va_end ()</pre> |
| DESCRIPTION | <p>This macro facilitates a normal return from the function whose variable argument list was referred to by the expansion of <i>va_start()</i> that initialized the va_list object.</p> <p><i>va_end()</i> may modify the va_list object so that it is no longer usable (without an intervening invocation of <i>va_start()</i>). If there is no corresponding invocation of the <i>va_start()</i> macro, or if the <i>va_end()</i> macro is not invoked before the return, the behavior is undefined.</p> |
| RETURNS | N/A |
| SEE ALSO | ansiStdarg |

va_start()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>va_start()</i> – initialize a va_list object for use by <i>va_arg()</i> and <i>va_end()</i> |
| SYNOPSIS | <pre>void va_start ()</pre> |
| DESCRIPTION | <p>This macro initializes an object of type va_list (<i>ap</i>) for subsequent use by <i>va_arg()</i> and <i>va_end()</i>. The parameter <i>parmN</i> is the identifier of the rightmost parameter in the variable parameter list in the function definition (the one just before the <i>, ...</i>). If <i>parmN</i> is declared with the register storage class with a function or array type, or with a type that is not compatible with the type that results after application of the default argument promotions, the behavior is undefined.</p> |
| RETURNS | N/A |
| SEE ALSO | ansiStdarg |

valloc()

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>valloc()</i> – allocate memory on a page boundary |
| SYNOPSIS | <pre>void * valloc (unsigned size /* number of bytes to allocate */)</pre> |
| DESCRIPTION | This routine allocates a buffer of <i>size</i> bytes from the system memory partition. Additionally, it insures that the allocated buffer begins on a page boundary. Page sizes are architecture-dependent. |
| RETURNS | A pointer to the newly allocated block, or NULL if the buffer could not be allocated or the memory management unit (MMU) support library has not been initialized. |
| ERRNO | S_memLib_PAGE_SIZE_UNAVAILABLE |
| SEE ALSO | memLib |

version()

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>version()</i> – print VxWorks version information |
| SYNOPSIS | <pre>void version (void)</pre> |
| DESCRIPTION | This command prints the VxWorks version number, the date this copy of VxWorks was made, and other pertinent information. |
| EXAMPLE | <pre>-> version VxWorks (for Mizar 7170) version 5.1 Kernel: WIND version 2.1. Made on Tue Jul 27 20:26:23 CDT 1997. Boot line: enp(0,0)host:/usr/wpwr/target/config/mz7170/vxWorks e=90.0.0.50 h=90.0.0.4 u=target</pre> |
| RETURNS | N/A |
| SEE ALSO | usrLib , <i>VxWorks Programmer's Guide: Target Shell</i> , windsh , <i>Tornado User's Guide: Shell</i> |

vfdprintf()

NAME *vfdprintf()* – write a string formatted with a variable argument list to a file descriptor

SYNOPSIS

```
int vfdprintf
(
    int          fd,      /* file descriptor to print to */
    const char * fmt,    /* format string for print */
    va_list      vaList  /* optional arguments to format */
)
```

DESCRIPTION This routine prints a string formatted with a variable argument list to a specified file descriptor. It is identical to *fdprintf()*, except that it takes the variable arguments to be formatted as a list *vaList* of type **va_list** rather than as in-line arguments.

RETURNS The number of characters output, or ERROR if there is an error during output.

SEE ALSO *fioLib*, *fdprintf()*

vfprintf()

NAME *vfprintf()* – write a formatted string to a stream (ANSI)

SYNOPSIS

```
int vfprintf
(
    FILE *      fp,      /* stream to write to */
    const char * fmt,    /* format string */
    va_list     vaList  /* arguments to format string */
)
```

DESCRIPTION This routine is equivalent to *fprintf()*, except that it takes the variable arguments to be formatted from a list *vaList* of type **va_list** rather than from in-line arguments.

INCLUDE FILES *stdio.h*

RETURNS The number of characters written, or a negative value if an output error occurs.

SEE ALSO *ansiStdio*, *fprintf()*

vmBaseGlobalMapInit()

NAME *vmBaseGlobalMapInit()* – initialize global mapping

SYNOPSIS

```

VM_CONTEXT_ID vmBaseGlobalMapInit
(
    PHYS_MEM_DESC * pMemDescArray,      /* pointer to array of mem descsc */
    int             numDescArrayElements, /* no. of elements */
                                     /* in pMemDescArray */
    BOOL            enable               /* enable virtual memory */
)

```

DESCRIPTION This routine creates and installs a virtual memory context with mappings defined for each contiguous memory segment defined in *pMemDescArray*. In the standard VxWorks configuration, an instance of **PHYS_MEM_DESC** (called **sysPhysMemDesc**) is defined in **sysLib.c**; the variable is passed to *vmBaseGlobalMapInit()* by the system configuration mechanism.

The physical memory descriptor also contains state information used to initialize the state information in the MMU's translation table for that memory segment. The following state bits may be or'ed together:

| | | |
|---------------------------|-------------------------------|--------------------------|
| VM_STATE_VALID | VM_STATE_VALID_NOT | valid/invalid |
| VM_STATE_WRITABLE | VM_STATE_WRITABLE_NOT | writable/write-protected |
| VM_STATE_CACHEABLE | VM_STATE_CACHEABLE_NOT | cacheable/not-cacheable |

Additionally, mask bits are or'ed together in the **initialStateMask** structure element to describe which state bits are being specified in the **initialState** structure element:

```

VM_STATE_MASK_VALID
VM_STATE_MASK_WRITABLE
VM_STATE_MASK_CACHEABLE

```

If *enable* is TRUE, the MMU is enabled upon return.

RETURNS A pointer to a newly created virtual memory context, or NULL if memory cannot be mapped.

SEE ALSO *vmBaseLibInit()*

vmBaseLibInit()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>vmBaseLibInit()</i> – initialize base virtual memory support |
| SYNOPSIS | <pre>STATUS vmBaseLibInit (int pageSize /* size of page */)</pre> |
| DESCRIPTION | This routine initializes the virtual memory context class and module-specific data structures. It is called only once during system initialization, and should be followed with a call to <i>vmBaseGlobalMapInit()</i> , which initializes and enables the MMU. |
| RETURNS | OK. |
| SEE ALSO | <i>vmBaseLib</i> , <i>vmBaseGlobalMapInit()</i> |

vmBasePageSizeGet()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------|
| NAME | <i>vmBasePageSizeGet()</i> – return the page size |
| SYNOPSIS | <pre>int vmBasePageSizeGet (void)</pre> |
| DESCRIPTION | This routine returns the architecture-dependent page size. This routine is callable from interrupt level. |
| RETURNS | The page size of the current architecture. |
| SEE ALSO | <i>vmBaseLib</i> |

vmBaseStateSet()

NAME *vmBaseStateSet()* – change the state of a block of virtual memory

SYNOPSIS

```
STATUS vmBaseStateSet
(
    VM_CONTEXT_ID context, /* context - NULL == currentContext */
    void *        pVirtual, /* virtual address to modify state of */
    int          len, /* len of virtual space to modify state of */
    UINT         stateMask, /* state mask */
    UINT         state /* state */
)
```

DESCRIPTION This routine changes the state of a block of virtual memory. Each page of virtual memory has at least three elements of state information: validity, writability, and cacheability. Specific architectures may define additional state information; see **vmLib.h** for additional architecture-specific states. Memory accesses to a page marked as invalid will result in an exception. Pages may be invalidated to prevent them from being corrupted by invalid references. Pages may be defined as read-only or writable, depending on the state of the writable bits. Memory accesses to pages marked as not-cacheable will always result in a memory cycle, bypassing the cache. This is useful for multiprocessing, multiple bus masters, and hardware control registers.

The following states are provided and may be or'ed together in the state parameter:

| | | |
|--------------------|------------------------|--------------------------|
| VM_STATE_VALID | VM_STATE_VALID_NOT | valid/invalid |
| VM_STATE_WRITABLE | VM_STATE_WRITABLE_NOT | writable/write-protected |
| VM_STATE_CACHEABLE | VM_STATE_CACHEABLE_NOT | cacheable/not-cacheable |

Additionally, the following masks are provided so that only specific states may be set. These may be or'ed together in the **stateMask** parameter.

```
VM_STATE_MASK_VALID
VM_STATE_MASK_WRITABLE
VM_STATE_MASK_CACHEABLE
```

If *context* is specified as NULL, the current context is used.

This routine is callable from interrupt level.

RETURNS OK, or ERROR if the validation fails, *pVirtual* is not on a page boundary, *len* is not a multiple of the page size, or the architecture-dependent state set fails for the specified virtual address.

ERRNO S_vmLib_NOT_PAGE_ALIGNED, S_vmLib_BAD_STATE_PARAM, S_vmLib_BAD_MASK_PARAM

SEE ALSO **vmBaseLib**

vmContextCreate()

| | |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>vmContextCreate()</i> – create a new virtual memory context (VxVMI Opt.) |
| SYNOPSIS | <code>VM_CONTEXT_ID vmContextCreate (void)</code> |
| DESCRIPTION | <p>This routine creates a new virtual memory context. The newly created context does not become the current context until explicitly installed by a call to <i>vmCurrentSet()</i>. Modifications to the context state (mappings, state changes, etc.) may be performed on any virtual memory context, even if it is not the current context.</p> <p>This routine should not be called from interrupt level.</p> |
| AVAILABILITY | This routine is distributed as a component of the unbundled virtual memory support option, VxVMI. |
| RETURNS | A pointer to a new virtual memory context, or NULL if the allocation or initialization fails. |
| SEE ALSO | <code>vmLib</code> |

vmContextDelete()

| | |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>vmContextDelete()</i> – delete a virtual memory context (VxVMI Opt.) |
| SYNOPSIS | <pre>STATUS vmContextDelete (VM_CONTEXT_ID context)</pre> |
| DESCRIPTION | <p>This routine deallocates the underlying translation table associated with a virtual memory context. It does not free the physical memory already mapped to the virtual memory space.</p> <p>This routine should not be called from interrupt level.</p> |
| AVAILABILITY | This routine is distributed as a component of the unbundled virtual memory support option, VxVMI. |
| RETURNS | OK, or ERROR if <i>context</i> is not a valid context descriptor or if an error occurs deleting the translation table. |
| SEE ALSO | <code>vmLib</code> |

vmContextShow()

| | |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>vmContextShow()</i> – display the translation table for a context (VxVMI Opt.) |
| SYNOPSIS | <pre>STATUS vmContextShow (VM_CONTEXT_ID context /* context - NULL == currentContext */)</pre> |
| DESCRIPTION | <p>This routine displays the translation table for a specified context. If <i>context</i> is specified as NULL, the current context is displayed. Output is formatted to show blocks of virtual memory with consecutive physical addresses and the same state. State information shows the writable and cacheable states. If the block is in global virtual memory, the word "global" is appended to the line. Only virtual memory that has its valid state bit set is displayed.</p> <p>This routine should be used for debugging purposes only.</p> <p>Note that this routine cannot report non-standard architecture-dependent states.</p> |
| AVAILABILITY | This routine is distributed as a component of the unbundled virtual memory support option, VxVMI. |
| RETURNS | OK, or ERROR if the virtual memory context is invalid. |
| SEE ALSO | <i>vmShow</i> |

vmCurrentGet()

| | |
|---------------------|-----------------------------------------------------------------------------------------------------------------------|
| NAME | <i>vmCurrentGet()</i> – get the current virtual memory context (VxVMI Opt.) |
| SYNOPSIS | <pre>VM_CONTEXT_ID vmCurrentGet (void)</pre> |
| DESCRIPTION | <p>This routine returns the current virtual memory context.</p> <p>This routine is callable from interrupt level.</p> |
| AVAILABILITY | This routine is distributed as a component of the unbundled virtual memory support option, VxVMI. |
| RETURNS | The current virtual memory context, or NULL if no virtual memory context is installed. |
| SEE ALSO | <i>vmLib</i> |

vmCurrentSet()

| | |
|---------------------|-------------------------------------------------------------------------------------------------------------|
| NAME | <i>vmCurrentSet()</i> – set the current virtual memory context (VxVMI Opt.) |
| SYNOPSIS | <pre>STATUS vmCurrentSet (VM_CONTEXT_ID context /* context to install */)</pre> |
| DESCRIPTION | This routine installs a specified virtual memory context. This routine is callable from interrupt level. |
| AVAILABILITY | This routine is distributed as a component of the unbundled virtual memory support option, VxVMI. |
| RETURNS | OK, or ERROR if the validation or context switch fails. |
| SEE ALSO | vmLib |

vmEnable()

| | |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>vmEnable()</i> – enable or disable virtual memory (VxVMI Opt.) |
| SYNOPSIS | <pre>STATUS vmEnable (BOOL enable /* TRUE == enable MMU, FALSE == disable MMU */)</pre> |
| DESCRIPTION | This routine turns virtual memory on and off. Memory management should not be turned off once it is turned on except in the case of system shutdown. This routine is callable from interrupt level. |
| AVAILABILITY | This routine is distributed as a component of the unbundled virtual memory support option, VxVMI. |
| RETURNS | OK, or ERROR if the validation or architecture-dependent code fails. |
| SEE ALSO | vmLib |

vmGlobalInfoGet()

NAME *vmGlobalInfoGet()* – get global virtual memory information (VxVMI Opt.)

SYNOPSIS `UINT8 *vmGlobalInfoGet (void)`

DESCRIPTION This routine provides a description of those parts of the virtual memory space dedicated to global memory. The routine returns a pointer to an array of `UINT8`. Each element of the array corresponds to a block of virtual memory, the size of which is architecture-dependent and can be obtained with a call to *vmPageBlockSizeGet()*. To determine if a particular address is in global virtual memory, use the following code:

```
UINT8 *globalPageBlockArray = vmGlobalInfoGet ();
int pageBlockSize = vmPageBlockSizeGet ();

if (globalPageBlockArray[addr/pageBlockSize])
    ...
```

The array pointed to by the returned pointer is guaranteed to be static as long as no calls are made to *vmGlobalMap()* while the array is being examined. The information in the array can be used to determine what portions of the virtual memory space are available for use as private virtual memory within a virtual memory context.

This routine is callable from interrupt level.

AVAILABILITY This routine is distributed as a component of the unbundled virtual memory support option, VxVMI.

RETURNS A pointer to an array of `UINT8`.

SEE ALSO *vmLib*, *vmPageBlockSizeGet()*

vmGlobalMap()

NAME *vmGlobalMap()* – map physical pages to virtual space in shared global virtual memory (VxVMI Opt.)

SYNOPSIS `STATUS vmGlobalMap`
`(`
`void * virtualAddr, /* virtual address */`
`void * physicalAddr, /* physical address */`
`UINT len /* len of virtual and physical spaces */`
`)`

| | |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | This routine maps physical pages to virtual space that is shared by all virtual memory contexts. Calls to <i>vmGlobalMap()</i> should be made before any virtual memory contexts are created to insure that the shared global mappings are included in all virtual memory contexts. Mappings created with <i>vmGlobalMap()</i> after virtual memory contexts are created are not guaranteed to appear in all virtual memory contexts. After the call to <i>vmGlobalMap()</i> , the state of all pages in the the newly mapped virtual memory is unspecified and must be set with a call to <i>vmStateSet()</i> , once the initial virtual memory context is created. This routine should not be called from interrupt level. |
| AVAILABILITY | This routine is distributed as a component of the unbundled virtual memory support option, VxVMI. |
| RETURNS | OK, or ERROR if <i>virtualAddr</i> or <i>physicalAddr</i> are not on page boundaries, <i>len</i> is not a multiple of the page size, or the mapping fails. |
| ERRNO | S_vmLib_NOT_PAGE_ALIGNED |
| SEE ALSO | vmLib |

vmGlobalMapInit()

| | | | | | | | | | | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|--------------------|---------------|-------------------|-----------------------|--------------------------|--------------------|------------------------|-------------------------|
| NAME | <i>vmGlobalMapInit()</i> – initialize global mapping (VxVMI Opt.) | | | | | | | | | |
| SYNOPSIS | <pre>VM_CONTEXT_ID vmGlobalMapInit (PHYS_MEM_DESC * pMemDescArray, /* pointer to array of mem desc */ int numDescArrayElements, /* # of elements in pMemDescArray */ BOOL enable /* enable virtual memory */)</pre> | | | | | | | | | |
| DESCRIPTION | <p>This routine is a convenience routine that creates and installs a virtual memory context with global mappings defined for each contiguous memory segment defined in the physical memory descriptor array passed as an argument. The context ID returned becomes the current virtual memory context.</p> <p>The physical memory descriptor also contains state information used to initialize the state information in the MMU's translation table for that memory segment. The following state bits may be or'ed together:</p> <table><tr><td>VM_STATE_VALID</td><td>VM_STATE_VALID_NOT</td><td>valid/invalid</td></tr><tr><td>VM_STATE_WRITABLE</td><td>VM_STATE_WRITABLE_NOT</td><td>writable/write-protected</td></tr><tr><td>VM_STATE_CACHEABLE</td><td>VM_STATE_CACHEABLE_NOT</td><td>cacheable/not-cacheable</td></tr></table> | VM_STATE_VALID | VM_STATE_VALID_NOT | valid/invalid | VM_STATE_WRITABLE | VM_STATE_WRITABLE_NOT | writable/write-protected | VM_STATE_CACHEABLE | VM_STATE_CACHEABLE_NOT | cacheable/not-cacheable |
| VM_STATE_VALID | VM_STATE_VALID_NOT | valid/invalid | | | | | | | | |
| VM_STATE_WRITABLE | VM_STATE_WRITABLE_NOT | writable/write-protected | | | | | | | | |
| VM_STATE_CACHEABLE | VM_STATE_CACHEABLE_NOT | cacheable/not-cacheable | | | | | | | | |

Additionally, mask bits are or'ed together in the **initialStateMask** structure element to describe which state bits are being specified in the **initialState** structure element:

```
VM_STATE_MASK_VALID
VM_STATE_MASK_WRITABLE
VM_STATE_MASK_CACHEABLE
```

If the *enable* parameter is TRUE, the MMU is enabled upon return. The *vmGlobalMapInit()* routine should be called only after *vmLibInit()* has been called.

| | |
|---------------------|---------------------------------------------------------------------------------------------------|
| AVAILABILITY | This routine is distributed as a component of the unbundled virtual memory support option, VxVMI. |
| RETURNS | A pointer to a newly created virtual memory context, or NULL if the memory cannot be mapped. |
| SEE ALSO | vmLib |

vmLibInit()

| | |
|---------------------|-----------------------------------------------------------------------------------------------------------------|
| NAME | <i>vmLibInit()</i> – initialize the virtual memory support module (VxVMI Opt.) |
| SYNOPSIS | <pre>STATUS vmLibInit (int pageSize /* size of page */)</pre> |
| DESCRIPTION | This routine initializes the virtual memory context class. It is called only once during system initialization. |
| AVAILABILITY | This routine is distributed as a component of the unbundled virtual memory support option, VxVMI. |
| RETURNS | OK. |
| SEE ALSO | vmLib |

vmMap()

vmMap()**NAME** `vmMap()` – map physical space into virtual space (VxVMI Opt.)

SYNOPSIS

```

STATUS vmMap
(
    VM_CONTEXT_ID context,      /* context - NULL == currentContext */
    void *          virtualAddr, /* virtual address */
    void *          physicalAddr, /* physical address */
    UINT           len          /* len of virtual and physical spaces */
)

```

DESCRIPTION

This routine maps physical pages into a contiguous block of virtual memory. *virtualAddr* and *physicalAddr* must be on page boundaries, and *len* must be evenly divisible by the page size. After the call to `vmMap()`, the state of all pages in the newly mapped virtual memory is valid, writable, and cacheable.

The `vmMap()` routine can fail if the specified virtual address space conflicts with the translation tables of the global virtual memory space. The global virtual address space is architecture-dependent and is initialized at boot time with calls to `vmGlobalMap()` by `vmGlobalMapInit()`. If a conflict results, **errno** is set to `S_vmLib_ADDR_IN_GLOBAL_SPACE`. To avoid this conflict, use `vmGlobalInfoGet()` to ascertain which portions of the virtual address space are reserved for the global virtual address space. If *context* is specified as `NULL`, the current virtual memory context is used.

This routine should not be called from interrupt level.

AVAILABILITY This routine is distributed as a component of the unbundled virtual memory support option, VxVMI.

RETURNS OK, or ERROR if *virtualAddr* or *physicalAddr* are not on page boundaries, *len* is not a multiple of the page size, the validation fails, or the mapping fails.

ERRNO `S_vmLib_NOT_PAGE_ALIGNED`, `S_vmLib_ADDR_IN_GLOBAL_SPACE`

SEE ALSO `vmLib`

vmPageBlockSizeGet()

| | |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>vmPageBlockSizeGet()</i> – get the architecture-dependent page block size (VxVMI Opt.) |
| SYNOPSIS | <code>int vmPageBlockSizeGet (void)</code> |
| DESCRIPTION | <p>This routine returns the size of a page block for the current architecture. Each MMU architecture constructs translation tables such that a minimum number of pages are pre-defined when a new section of the translation table is built. This minimal group of pages is referred to as a "page block." This routine may be used in conjunction with <i>vmGlobalInfoGet()</i> to examine the layout of global virtual memory.</p> <p>This routine is callable from interrupt level.</p> |
| AVAILABILITY | This routine is distributed as a component of the unbundled virtual memory support option, VxVMI. |
| RETURNS | The page block size of the current architecture. |
| SEE ALSO | <i>vmLib</i> , <i>vmGlobalInfoGet()</i> |

vmPageSizeGet()

| | |
|---------------------|-------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>vmPageSizeGet()</i> – return the page size (VxVMI Opt.) |
| SYNOPSIS | <code>int vmPageSizeGet (void)</code> |
| DESCRIPTION | <p>This routine returns the architecture-dependent page size.</p> <p>This routine is callable from interrupt level.</p> |
| AVAILABILITY | This routine is distributed as a component of the unbundled virtual memory support option, VxVMI. |
| RETURNS | The page size of the current architecture. |
| SEE ALSO | <i>vmLib</i> |

vmShowInit()

| | |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>vmShowInit()</i> – include virtual memory show facility (VxVMI Opt.) |
| SYNOPSIS | <code>void vmShowInit (void)</code> |
| DESCRIPTION | This routine acts as a hook to include <i>vmContextShow()</i> . It is called automatically when the virtual memory show facility is configured into VxWorks using either of the following methods: <ul style="list-style-type: none">– If you use the configuration header files, define both <code>INCLUDE_MMU_FULL</code> and <code>INCLUDE_SHOW_ROUTINES</code> in <code>config.h</code>.– If you use the Tornado project facility, select <code>INCLUDE_MMU_FULL_SHOW</code>. |
| AVAILABILITY | This routine is distributed as a component of the unbundled virtual memory support option, VxVMI. |
| RETURNS | N/A |
| SEE ALSO | <code>vmShow</code> |

vmStateGet()

| | | | | | | | | | | |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------|---------------------------------|---------------|--------------------------------|------------------------------------|--------------------------|---------------------------------|-------------------------------------|-------------------------|
| NAME | <i>vmStateGet()</i> – get the state of a page of virtual memory (VxVMI Opt.) | | | | | | | | | |
| SYNOPSIS | <pre>STATUS vmStateGet (VM_CONTEXT_ID context, /* context - NULL == currentContext */ void * pPageAddr, /* virtual page addr */ UINT * pState /* where to return state */)</pre> | | | | | | | | | |
| DESCRIPTION | This routine extracts state bits with the following masks: <code>VM_STATE_MASK_VALID</code> <code>VM_STATE_MASK_WRITABLE</code> <code>VM_STATE_MASK_CACHEABLE</code> Individual states may be identified with the following constants: <table><tr><td><code>VM_STATE_VALID</code></td><td><code>VM_STATE_VALID_NOT</code></td><td>valid/invalid</td></tr><tr><td><code>VM_STATE_WRITABLE</code></td><td><code>VM_STATE_WRITABLE_NOT</code></td><td>writable/write-protected</td></tr><tr><td><code>VM_STATE_CACHEABLE</code></td><td><code>VM_STATE_CACHEABLE_NOT</code></td><td>cacheable/not-cacheable</td></tr></table> | <code>VM_STATE_VALID</code> | <code>VM_STATE_VALID_NOT</code> | valid/invalid | <code>VM_STATE_WRITABLE</code> | <code>VM_STATE_WRITABLE_NOT</code> | writable/write-protected | <code>VM_STATE_CACHEABLE</code> | <code>VM_STATE_CACHEABLE_NOT</code> | cacheable/not-cacheable |
| <code>VM_STATE_VALID</code> | <code>VM_STATE_VALID_NOT</code> | valid/invalid | | | | | | | | |
| <code>VM_STATE_WRITABLE</code> | <code>VM_STATE_WRITABLE_NOT</code> | writable/write-protected | | | | | | | | |
| <code>VM_STATE_CACHEABLE</code> | <code>VM_STATE_CACHEABLE_NOT</code> | cacheable/not-cacheable | | | | | | | | |

For example, to see if a page is writable, the following code would be used:

```
vmStateGet (vmContext, pageAddr, &state);
if ((state & VM_STATE_MASK_WRITABLE) & VM_STATE_WRITABLE)
    ...
```

If *context* is specified as NULL, the current virtual memory context is used.

This routine is callable from interrupt level.

| | |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AVAILABILITY | This routine is distributed as a component of the unbundled virtual memory support option, VxVMI. |
| RETURNS | OK, or ERROR if <i>pageAddr</i> is not on a page boundary, the validity check fails, or the architecture-dependent state get fails for the specified virtual address. |
| ERRNO | S_vmLib_NOT_PAGE_ALIGNED |
| SEE ALSO | vmLib |

vmStateSet()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>vmStateSet()</i> – change the state of a block of virtual memory (VxVMI Opt.) |
| SYNOPSIS | <pre>STATUS vmStateSet (VM_CONTEXT_ID context, /* context - NULL == currentContext */ void * pVirtual, /* virtual address to modify state of */ int len, /* len of virtual space to modify state of */ UINT stateMask, /* state mask */ UINT state /* state */)</pre> |
| DESCRIPTION | <p>This routine changes the state of a block of virtual memory. Each page of virtual memory has at least three elements of state information: validity, writability, and cacheability. Specific architectures may define additional state information; see vmLib.h for additional architecture-specific states. Memory accesses to a page marked as invalid will result in an exception. Pages may be invalidated to prevent them from being corrupted by invalid references. Pages may be defined as read-only or writable, depending on the state of the writable bits. Memory accesses to pages marked as not-cacheable will always result in a memory cycle, bypassing the cache. This is useful for multiprocessing, multiple bus masters, and hardware control registers.</p> |

The following states are provided and may be or'ed together in the state parameter:

| | | |
|--------------------|------------------------|--------------------------|
| VM_STATE_VALID | VM_STATE_VALID_NOT | valid/invalid |
| VM_STATE_WRITABLE | VM_STATE_WRITABLE_NOT | writable/write-protected |
| VM_STATE_CACHEABLE | VM_STATE_CACHEABLE_NOT | cacheable/not-cacheable |

Additionally, the following masks are provided so that only specific states may be set. These may be or'ed together in the **stateMask** parameter.

VM_STATE_MASK_VALID
VM_STATE_MASK_WRITABLE
VM_STATE_MASK_CACHEABLE

If *context* is specified as NULL, the current context is used.

This routine is callable from interrupt level.

| | |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AVAILABILITY | This routine is distributed as a component of the unbundled virtual memory support option, VxVMI. |
| RETURNS | OK or, ERROR if the validation fails, <i>pVirtual</i> is not on a page boundary, <i>len</i> is not a multiple of page size, or the architecture-dependent state set fails for the specified virtual address. |
| ERRNO | S_vmLib_NOT_PAGE_ALIGNED, S_vmLib_BAD_STATE_PARAM, S_vmLib_BAD_MASK_PARAM |

vmTranslate()

NAME *vmTranslate()* – translate a virtual address to a physical address (VxVMI Opt.)SYNOPSIS

```
STATUS vmTranslate
(
    VM_CONTEXT_ID context,      /* context - NULL == currentContext */
    void *          virtualAddr, /* virtual address */
    void *          *physicalAddr /* place to put result */
)
```

DESCRIPTION This routine retrieves mapping information for a virtual address from the page translation tables. If the specified virtual address has never been mapped, the returned status can be either OK or ERROR; however, if it is OK, then the returned physical address will be -1. If *context* is specified as NULL, the current context is used.

This routine is callable from interrupt level.

AVAILABILITY This routine is distributed as a component of the unbundled virtual memory support option, VxVMI.

RETURNS OK, or ERROR if the validation or translation fails.

SEE ALSO `vmLib`

vprintf()

NAME *vprintf()* – write a string formatted with a variable argument list to standard output (ANSI)SYNOPSIS

```
int vprintf
(
    const char * fmt, /* format string to write */
    va_list    vaList /* arguments to format */
)
```

vsprintf()

- DESCRIPTION** This routine prints a string formatted with a variable argument list to standard output. It is identical to *printf()*, except that it takes the variable arguments to be formatted as a list *vaList* of type **va_list** rather than as in-line arguments.
- RETURNS** The number of characters output, or ERROR if there is an error during output.
- SEE ALSO** *fcntlLib, printf()*, *American National Standard for Information Systems – Programming Language – C, ANSI X3.159-1989: Input/Output (stdio.h)*

vsprintf()

- NAME** *vsprintf()* – write a string formatted with a variable argument list to a buffer (ANSI)
- SYNOPSIS**
- ```
int vsprintf
(
 char * buffer, /* buffer to write to */
 const char * fmt, /* format string */
 va_list vaList /* optional arguments to format */
)
```
- DESCRIPTION** This routine copies a string formatted with a variable argument list to a specified buffer. This routine is identical to *sprintf()*, except that it takes the variable arguments to be formatted as a list *vaList* of type **va\_list** rather than as in-line arguments.
- RETURNS** The number of characters copied to *buffer*, not including the NULL terminator.
- SEE ALSO** *fcntlLib, sprintf()*, *American National Standard for Information Systems – Programming Language – C, ANSI X3.159-1989: Input/Output (stdio.h)*

***vxMemArchProbe()***

- NAME** *vxMemArchProbe()* – architecture specific part of vxMemProbe
- SYNOPSIS**
- ```
STATUS vxMemArchProbe
(
    char * adrs, /* address to be probed */
    int   mode, /* VX_READ or VX_WRITE */
    int   length, /* 1, 2, 4, or 8 */
    char * pVal /* where to return value, or ptr to value to be written */
)
```

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | This is the routine implementing the architecture specific part of the vxMemProbe routine. It traps the relevant exceptions while accessing the specified address. If an exception occurs, then the result will be ERROR. If no exception occurs then the result will be OK. |
| RETURNS | OK or ERROR if an exception occurred during access. |
| SEE ALSO | vxLib |

vxMemProbe()

NAME *vxMemProbe()* – probe an address for a bus error

SYNOPSIS

```
STATUS vxMemProbe
(
    char * adrs,    /* address to be probed */
    int   mode,    /* VX_READ or VX_WRITE */
    int   length,  /* 1, 2, 4, or 8 */
    char * pVal    /* where to return value, or ptr to value to be written */
)
```

DESCRIPTION

This routine probes a specified address to see if it is readable or writable, as specified by *mode*. The address is read or written as 1, 2, or 4 bytes, as specified by *length* (values other than 1, 2, or 4 yield unpredictable results). If the probe is a **VX_READ** (0), the value read is copied to the location pointed to by *pVal*. If the probe is a **VX_WRITE** (1), the value written is taken from the location pointed to by *pVal*. In either case, *pVal* should point to a value of 1, 2, or 4 bytes, as specified by *length*.

Note that only bus errors are trapped during the probe, and that the access must otherwise be valid (i.e., it must not generate an address error).

EXAMPLE

```
testMem (adrs)
    char *adrs;
    {
    char testW = 1;
    char testR;
    if (vxMemProbe (adrs, VX_WRITE, 1, &testW) == OK)
        printf ("value %d written to adrs %x\n", testW, adrs);
    if (vxMemProbe (adrs, VX_READ, 1, &testR) == OK)
        printf ("value %d read from adrs %x\n", testR, adrs);
    }
```

vxMemProbeAsi()

- MODIFICATION** The BSP can modify the behaviour of *vxMemProbe()* by supplying an alternate routine and placing the address in the global variable `_func_vxMemProbeHook`. The BSP routine will be called instead of the architecture specific routine *vxMemArchProbe()*.
- RETURNS** OK, or ERROR if the probe caused a bus error or was misaligned.
- SEE ALSO** *vxLib*, *vxMemArchProbe()*

vxMemProbeAsi()

NAME *vxMemProbeAsi()* – probe address in ASI space for bus error (SPARC)

SYNOPSIS

```
STATUS vxMemProbeAsi
(
    char * adrs, /* address to be probed */
    int mode, /* VX_READ or VX_WRITE */
    int length, /* 1, 2, 4, or 8 */
    char * pVal, /* where to return value, or ptr to value to be written */
    int adrsAsi /* ASI field of address to be probed */
)
```

DESCRIPTION This routine probes the specified address to see if it is readable or writable, as specified by *mode*. The address will be read/written as 1, 2, 4, or 8 bytes as specified by *length* (values other than 1, 2, 4, or 8 return ERROR). If the probe is a `VX_READ` (0), then the value read will be returned in the location pointed to by *pVal*. If the probe is a `VX_WRITE` (1), then the value written will be taken from the location pointed to by *pVal*. In either case, *pVal* should point to a value of the appropriate length, 1, 2, 4, or 8 bytes, as specified by *length*.

The fifth parameter *adrsAsi* is the ASI parameter used to modify the *adrs* parameter.

EXAMPLE

```
testMem (adrs)
    char *adrs;
    {
    char testW = 1;
    char testR;
    if (vxMemProbeAsi (adrs, VX_WRITE, 1, &testW) == OK)
        printf ("value %d written to adrs %x\n", testW, adrs);
    if (vxMemProbeAsi (adrs, VX_READ, 1, &testR) == OK)
        printf ("value %d read from adrs %x\n", testR, adrs);
    }
```

RETURNS OK, or ERROR if the probe caused a bus error or was misaligned.

SEE ALSO *vxLib*

vxPowerDown()

| | |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>vxPowerDown()</i> – place the processor in reduced-power mode (PowerPC) |
| SYNOPSIS | UINT32 <i>vxPowerDown</i> (void) |
| DESCRIPTION | This routine activates the reduced-power mode if power management is enabled. It is called by the scheduler when the kernel enters the idle loop. The power management mode is selected by <i>vxPowerModeSet()</i> . |
| RETURNS | OK, or ERROR if power management is not supported or if external interrupts are disabled. |
| SEE ALSO | <i>vxLib</i> , <i>vxPowerModeSet()</i> , <i>vxPowerModeGet()</i> STATUS <i>vxPowerDown</i> (void) |

vxPowerModeGet()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------|
| NAME | <i>vxPowerModeGet()</i> – get the power management mode (PowerPC) |
| SYNOPSIS | UINT32 <i>vxPowerModeGet</i> (void) |
| DESCRIPTION | This routine returns the power management mode set by <i>vxPowerModeSet()</i> . |
| RETURNS | The power management mode, or ERROR if no mode has been selected or if power management is not supported. |
| SEE ALSO | <i>vxLib</i> , <i>vxPowerModeSet()</i> , <i>vxPowerDown()</i> |

vxPowerModeSet()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>vxPowerModeSet()</i> – set the power management mode (PowerPC) |
| SYNOPSIS | <pre>STATUS vxPowerModeSet (UINT32 mode /* power management mode to select */)</pre> |
| DESCRIPTION | <p>This routine selects the power management mode to be activated when <i>vxPowerDown()</i> is called. <i>vxPowerModeSet()</i> is normally called in the BSP initialization routine <i>sysHwInit()</i>.</p> <p>Power management modes include the following:</p> <p>VX_POWER_MODE_DISABLE (0x1) Power management is disabled; this prevents the MSR(POW) bit from being set (all PPC).</p> <p>VX_POWER_MODE_FULL (0x2) All CPU units are active while the kernel is idle (PPC603, PPCEC603 and PPC860 only).</p> <p>VX_POWER_MODE_DOZE (0x4) Only the decremter, data cache, and bus snooping are active while the kernel is idle (PPC603, PPCEC603 and PPC860).</p> <p>VX_POWER_MODE_NAP (0x8) Only the decremter is active while the kernel is idle (PPC603, PPCEC603 and PPC604).</p> <p>VX_POWER_MODE_SLEEP (0x10) All CPU units are inactive while the kernel is idle (PPC603, PPCEC603 and PPC860 – not recommended for the PPC603 and PPCEC603 architecture).</p> <p>VX_POWER_MODE_DEEP_SLEEP (0x20) All CPU units are inactive while the kernel is idle (PPC860 only – not recommended).</p> <p>VX_POWER_MODE_DPM (0x40) Dynamic Power Management Mode (PPC603 and PPCEC603 only).</p> <p>VX_POWER_MODE_DOWN (0x80) Only a hard reset causes an exit from power-down low power mode (PPC860 only – not recommended).</p> |
| RETURNS | OK, or ERROR if <i>mode</i> is incorrect or not supported by the processor. |
| SEE ALSO | <i>vxLib</i> , <i>vxPowerModeGet()</i> , <i>vxPowerDown()</i> |

vxSSDisable()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------|
| NAME | <i>vxSSDisable()</i> – disable the superscalar dispatch (MC68060) |
| SYNOPSIS | <code>void vxSSDisable (void)</code> |
| DESCRIPTION | This function resets the ESS bit of the Processor Configuration Register (PCR) to disable the superscalar dispatch. |
| RETURNS | N/A |
| SEE ALSO | <code>vxLib</code> |

vxSSEnable()

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------|
| NAME | <i>vxSSEnable()</i> – enable the superscalar dispatch (MC68060) |
| SYNOPSIS | <code>void vxSSEnable (void)</code> |
| DESCRIPTION | This function sets the ESS bit of the Processor Configuration Register (PCR) to enable the superscalar dispatch. |
| RETURNS | N/A |
| SEE ALSO | <code>vxLib</code> |

vxTas()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>vxTas()</i> – C-callable atomic test-and-set primitive |
| SYNOPSIS | <pre>BOOL vxTas (void * address /* address to test and set */)</pre> |
| DESCRIPTION | This routine provides a C-callable interface to a test-and-set instruction. The instruction is executed on the specified address. The architecture test-and-set instruction is: |

VXWBSem::VXWBSem()

68K: **tas**
 SPARC: **ldstub**
 i960: **atmod**
 ARM **swpb**

This routine is equivalent to *sysBusTas()* in *sysLib*.

| | |
|--------------------|-------------------------------------------------------------------------------------------------|
| BUGS (MIPS) | Only Kseg0 and Kseg1 addresses are accepted; other addresses always return FALSE. |
| RETURNS | TRUE if the value had not been set (but is now), or FALSE if the value was set already. |
| SEE ALSO | <i>vxLib</i> , <i>sysBusTas()</i> |

VXWBSem::VXWBSem()

NAME *VXWBSem::VXWBSem()* – create and initialize a binary semaphore (WFC Opt.)

SYNOPSIS

```
VXWBSem
(
    int          opts,
    SEM_B_STATE iState
)
```

DESCRIPTION This routine allocates and initializes a binary semaphore. The semaphore is initialized to the state *iState*: either **SEM_FULL** (1) or **SEM_EMPTY** (0).

The *opts* parameter specifies the queuing style for blocked tasks. Tasks can be queued on a priority basis or a first-in-first-out basis. These options are **SEM_Q_PRIORITY** and **SEM_Q_FIFO**, respectively.

Binary semaphores are the most versatile, efficient, and conceptually simple type of semaphore. They can be used to: (1) control mutually exclusive access to shared devices or data structures, or (2) synchronize multiple tasks, or task-level and interrupt-level processes. Binary semaphores form the foundation of numerous VxWorks facilities.

A binary semaphore can be viewed as a cell in memory whose contents are in one of two states, full or empty. When a task takes a binary semaphore, using *VXWSem::take()*, subsequent action depends on the state of the semaphore:

- (1) If the semaphore is full, the semaphore is made empty, and the calling task continues executing.
- (2) If the semaphore is empty, the task is blocked, pending the availability of the semaphore. If a timeout is specified and the timeout expires, the pended task is removed from the queue of pended tasks and enters the ready state with an **ERROR**

status. A pended task is ineligible for CPU allocation. Any number of tasks may be pended simultaneously on the same binary semaphore.

When a task gives a binary semaphore, using **VXWSem::give()**, the next available task in the pend queue is unblocked. If no task is pending on this semaphore, the semaphore becomes full. Note that if a semaphore is given, and a task is unblocked that is of higher priority than the task that called **VXWSem::give()**, the unblocked task preempts the calling task.

MUTUAL EXCLUSION

To use a binary semaphore as a means of mutual exclusion, first create it with an initial state of full.

Then guard a critical section or resource by taking the semaphore with **VXWSem::take()**, and exit the section or release the resource by giving the semaphore with **VXWSem::give()**.

While there is no restriction on the same semaphore being given, taken, or flushed by multiple tasks, it is important to ensure the proper functionality of the mutual-exclusion construct. While there is no danger in any number of processes taking a semaphore, the giving of a semaphore should be more carefully controlled. If a semaphore is given by a task that did not take it, mutual exclusion could be lost.

SYNCHRONIZATION

To use a binary semaphore as a means of synchronization, create it with an initial state of empty. A task blocks by taking a semaphore at a synchronization point, and it remains blocked until the semaphore is given by another task or interrupt service routine.

Synchronization with interrupt service routines is a particularly common need. Binary semaphores can be given, but not taken, from interrupt level. Thus, a task can block at a synchronization point with **VXWSem::take()**, and an interrupt service routine can unblock that task with **VXWSem::give()**.

A **semFlush()** on a binary semaphore atomically unblocks all pended tasks in the semaphore queue; that is, all tasks are unblocked at once, before any actually execute.

CAVEATS

There is no mechanism to give back or reclaim semaphores automatically when tasks are suspended or deleted. Such a mechanism, though desirable, is not currently feasible. Without explicit knowledge of the state of the guarded resource or region, reckless automatic reclamation of a semaphore could leave the resource in a partial state. Thus, if a task ceases execution unexpectedly, as with a bus error, currently owned semaphores will not be given back, effectively leaving a resource permanently unavailable. The mutual-exclusion semaphores provided by **VXWMSem** offer protection from unexpected task deletion.

RETURNS

N/A

SEE ALSO

VXWSem

VXWCSem::VXWCSem()

NAME VXWCSem::VXWCSem() – create and initialize a counting semaphore (WFC Opt.)

SYNOPSIS

```
VXWCSem
(
    int opts,
    int count
)
```

DESCRIPTION This routine allocates and initializes a counting semaphore. The semaphore is initialized to the specified initial count.

The *opts* parameter specifies the queuing style for blocked tasks. Tasks may be queued on a priority basis or a first-in-first-out basis. These options are **SEM_Q_PRIORITY** and **SEM_Q_FIFO**, respectively.

A counting semaphore may be viewed as a cell in memory whose contents keep track of a count. When a task takes a counting semaphore, using *VXWSem::take()*, subsequent action depends on the state of the count:

- (1) If the count is non-zero, it is decremented and the calling task continues executing.
- (2) If the count is zero, the task is blocked, pending the availability of the semaphore. If a timeout is specified and the timeout expires, the pended task is removed from the queue of pended tasks and enters the ready state with an **ERROR** status. A pended task is ineligible for CPU allocation. Any number of tasks may be pended simultaneously on the same counting semaphore.

When a task gives a semaphore, using *VXWSem::give()*, the next available task in the pend queue is unblocked. If no task is pending on this semaphore, the semaphore count is incremented. Note that if a semaphore is given, and a task is unblocked that is of higher priority than the task that called *VXWSem::give()*, the unblocked task preempts the calling task.

A *VXWSem::flush()* on a counting semaphore atomically unblocks all pended tasks in the semaphore queue. Thus, all tasks are made ready before any task actually executes. The count of the semaphore remains unchanged.

INTERRUPT USAGE Counting semaphores may be given but not taken from interrupt level.

CAVEATS There is no mechanism to give back or reclaim semaphores automatically when tasks are suspended or deleted. Such a mechanism, though desirable, is not currently feasible. Without explicit knowledge of the state of the guarded resource or region, reckless automatic reclamation of a semaphore could leave the resource in a partial state. Thus, if a task ceases execution unexpectedly, as with a bus error, currently owned semaphores are not given back, effectively leaving a resource permanently unavailable. The

mutual-exclusion semaphores provided by **VXWMSem** offer protection from unexpected task deletion.

RETURNS N/A

VXWList::add()

NAME ***VXWList::add()*** – add a node to the end of list (WFC Opt.)

SYNOPSIS

```
void add
(
    NODE * pNode
)
```

DESCRIPTION This routine adds a specified node to the end of the list.

RETURNS N/A

SEE ALSO **VXWList**

VXWList::concat()

NAME ***VXWList::concat()*** – concatenate two lists (WFC Opt.)

SYNOPSIS

```
void concat
(
    VXWList &aList
)
```

DESCRIPTION This routine concatenates the specified list to the end of the current list. The specified list is left empty. Either list (or both) can be empty at the beginning of the operation.

RETURNS N/A

SEE ALSO **VXWList**

VXWList::count()

NAME *VXWList::count()* – report the number of nodes in a list (WFC Opt.)

SYNOPSIS `int count ()`

DESCRIPTION This routine returns the number of nodes in a specified list.

RETURNS The number of nodes in the list.

SEE ALSO *VXWList*

VXWList::extract()

NAME *VXWList::extract()* – extract a sublist from list (WFC Opt.)

SYNOPSIS `LIST extract
(
 NODE * pStart,
 NODE * pEnd
)`

DESCRIPTION This routine extracts the sublist that starts with *pStart* and ends with *pEnd*. It returns the extracted list.

RETURNS The extracted sublist.

SEE ALSO *VXWList*

VXWList::find()

NAME *VXWList::find()* – find a node in list (WFC Opt.)

SYNOPSIS `int find
(
 NODE * pNode
) const`

DESCRIPTION This routine returns the node number of a specified node (the first node is 1).

RETURNS The node number, or ERROR if the node is not found.

SEE ALSO VXWList

VXWList::first()

NAME *VXWList::first()* – find first node in list (WFC Opt.)

SYNOPSIS `NODE * first ()`

DESCRIPTION This routine finds the first node in its list.

RETURNS A pointer to the first node in the list, or NULL if the list is empty.

SEE ALSO VXWList

VXWList::get()

NAME *VXWList::get()* – delete and return the first node from list (WFC Opt.)

SYNOPSIS `NODE * get ()`

DESCRIPTION This routine gets the first node from its list, deletes the node from the list, and returns a pointer to the node gotten.

RETURNS A pointer to the node gotten, or NULL if the list is empty.

SEE ALSO VXWList

VXWList::insert()

VXWList::insert()

NAME *VXWList::insert()* – insert a node in list after a specified node (WFC Opt.)

SYNOPSIS

```
void insert  
(  
    NODE * pPrev,  
    NODE * pNode  
)
```

DESCRIPTION This routine inserts a specified node into the list. The new node is placed following the list node *pPrev*. If *pPrev* is NULL, the node is inserted at the head of the list.

RETURNS N/A

SEE ALSO *VXWList*

VXWList::last()

NAME *VXWList::last()* – find the last node in list (WFC Opt.)

SYNOPSIS

```
NODE * last ()
```

DESCRIPTION This routine finds the last node in its list.

RETURNS A pointer to the last node in the list, or NULL if the list is empty.

SEE ALSO *VXWList*

VXWList::next()

NAME *VXWList::next()* – find the next node in list (WFC Opt.)

SYNOPSIS

```
NODE * next  
(  
    NODE * pNode  
) const
```

DESCRIPTION This routine locates the node immediately following a specified node.

RETURNS A pointer to the next node in the list, or NULL if there is no next node.

SEE ALSO VXWList

VXWList::nStep()

NAME **VXWList::nStep()** – find a list node *nStep* steps away from a specified node (WFC Opt.)

SYNOPSIS

```
NODE * nStep
(
    NODE * pNode,
    int   nStep
) const
```

DESCRIPTION This routine locates the node *nStep* steps away in either direction from a specified node. If *nStep* is positive, it steps toward the tail. If *nStep* is negative, it steps toward the head. If the number of steps is out of range, NULL is returned.

RETURNS A pointer to the node *nStep* steps away, or NULL if the node is out of range.

SEE ALSO VXWList

VXWList::nth()

NAME **VXWList::nth()** – find the Nth node in a list (WFC Opt.)

SYNOPSIS

```
NODE * nth
(
    int nodeNum
) const
```

DESCRIPTION This routine returns a pointer to the node specified *nodeNum* where the first node in the list is numbered 1. The search is optimized by searching forward from the beginning if the node is closer to the head, and searching back from the end if it is closer to the tail.

RETURNS A pointer to the Nth node, or NULL if there is no Nth node.

SEE ALSO VXWList

VXWList::previous()

VXWList::previous()

NAME *VXWList::previous()* – find the previous node in list (WFC Opt.)

SYNOPSIS

```
NODE * previous
(
    NODE * pNode
) const
```

DESCRIPTION This routine locates the node immediately preceding the node pointed to by *pNode*.

RETURNS A pointer to the previous node in the list, or NULL if there is no previous node.

SEE ALSO *VXWList*

VXWList::remove()

NAME *VXWList::remove()* – delete a specified node from list (WFC Opt.)

SYNOPSIS

```
void remove
(
    NODE * pNode
)
```

DESCRIPTION This routine deletes a specified node from its list.

RETURNS N/A

SEE ALSO *VXWList*

VXWList::VXWList()

NAME *VXWList::VXWList()* – initialize a list (WFC Opt.)

SYNOPSIS

```
VXWList ()
```

DESCRIPTION This constructor initializes a list as an empty list.

RETURNS N/A
SEE ALSO VXWList

VXWList::VXWList()

NAME *VXWList::VXWList()* – initialize a list as a copy of another (WFC Opt.)

SYNOPSIS

```
VXWList  
(  
    const VXWList &  
)
```

DESCRIPTION This constructor builds a new list as a copy of an existing list.

RETURNS N/A

SEE ALSO VXWList

VXWList::~~VXWList()

NAME *VXWList::~~VXWList()* – free up a list (WFC Opt.)

SYNOPSIS

```
~VXWList ()
```

DESCRIPTION This destructor frees up memory used for nodes.

RETURNS N/A

SEE ALSO VXWList

VXWMemPart::addToPool()

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | VXWMemPart::addToPool() – add memory to a memory partition (WFC Opt.) |
| SYNOPSIS | <pre>STATUS addToPool (char * pool, unsigned poolSize)</pre> |
| DESCRIPTION | This routine adds memory to its memory partition. The new memory added need not be contiguous with memory previously assigned to the partition. |
| RETURNS | OK or ERROR. |
| SEE ALSO | VXWMemPart |

VXWMemPart::alignedAlloc()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | VXWMemPart::alignedAlloc() – allocate aligned memory from partition (WFC Opt.) |
| SYNOPSIS | <pre>void * alignedAlloc (unsigned nBytes, unsigned alignment)</pre> |
| DESCRIPTION | This routine allocates a buffer of size <i>nBytes</i> from its partition. Additionally, it ensures that the allocated buffer begins on a memory address evenly divisible by <i>alignment</i> . The <i>alignment</i> parameter must be a power of 2. |
| RETURNS | A pointer to the newly allocated block, or NULL if the buffer cannot be allocated. |
| SEE ALSO | VXWMemPart |

VXWMemPart::alloc()

NAME *VXWMemPart::alloc()* – allocate a block of memory from partition (WFC Opt.)

SYNOPSIS

```
void * alloc  
(  
    unsigned nBytes  
)
```

DESCRIPTION This routine allocates a block of memory from its partition. The size of the block allocated is equal to or greater than *nBytes*.

RETURNS A pointer to a block, or NULL if the call fails.

SEE ALSO *VXWMemPart::free()*

VXWMemPart::findMax()

NAME *VXWMemPart::findMax()* – find the size of the largest available free block (WFC Opt.)

SYNOPSIS

```
int findMax ()
```

DESCRIPTION This routine searches for the largest block in the memory partition free list and returns its size.

RETURNS The size, in bytes, of the largest available block.

SEE ALSO *VXWMemPart*

VXWMemPart::free()

NAME *VXWMemPart::free()* – free a block of memory in partition (WFC Opt.)

SYNOPSIS

```
STATUS free  
(  
    char * pBlock  
)
```

VXWMemPart::info()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | This routine returns to the partition's free memory list a block of memory previously allocated with <i>VXWMemPart::alloc()</i> . |
| RETURNS | OK, or ERROR if the block is invalid. |
| SEE ALSO | <i>VXWMemPart::alloc()</i> |

VXWMemPart::info()

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>VXWMemPart::info()</i> – get partition information (WFC Opt.) |
| SYNOPSIS | <pre>STATUS info (MEM_PART_STATS * pPartStats) const</pre> |
| DESCRIPTION | This routine takes a pointer to a MEM_PART_STATS structure. All the parameters of the structure are filled in with the current partition information. |
| RETURNS | OK if the structure has valid data, otherwise ERROR. |
| SEE ALSO | <i>VXWMemPart::show()</i> |

VXWMemPart::options()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>VXWMemPart::options()</i> – set the debug options for memory partition (WFC Opt.) |
| SYNOPSIS | <pre>STATUS options (unsigned options)</pre> |
| DESCRIPTION | <p>This routine sets the debug options for its memory partition. Two kinds of errors are detected: attempts to allocate more memory than is available, and bad blocks found when memory is freed. In both cases, the error status is returned. There are four error-handling options that can be individually selected:</p> <p>MEM_ALLOC_ERROR_LOG_FLAG Log a message when there is an error in allocating memory.</p> |

MEM_ALLOC_ERROR_SUSPEND_FLAG

Suspend the task when there is an error in allocating memory (unless the task was spawned with the **VX_UNBREAKABLE** option, in which case it cannot be suspended).

MEM_BLOCK_ERROR_LOG_FLAG

Log a message when there is an error in freeing memory.

MEM_BLOCK_ERROR_SUSPEND_FLAG

Suspend the task when there is an error in freeing memory (unless the task was spawned with the **VX_UNBREAKABLE** option, in which case it cannot be suspended).

These options are discussed in detail in the library manual entry for **memLib**.

RETURNS OK or ERROR.

SEE ALSO **VXWMemPart**

VXWMemPart::realloc()

NAME ***VXWMemPart::realloc()*** – reallocate a block of memory in partition (WFC Opt.)

SYNOPSIS

```
void * realloc
(
    char * pBlock,
    int   nBytes
)
```

DESCRIPTION This routine changes the size of a specified block of memory and returns a pointer to the new block. The contents that fit inside the new size (or old size if smaller) remain unchanged. The memory alignment of the new block is not guaranteed to be the same as the original block.

If *pBlock* is NULL, this call is equivalent to ***VXWMemPart::alloc()***.

RETURNS A pointer to the new block of memory, or NULL if the call fails.

SEE ALSO **VXWMemPart**

VXWMemPart::show()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | VXWMemPart::show() – show partition blocks and statistics (WFC Opt.) |
| SYNOPSIS | <pre>STATUS show (int type = 0) const</pre> |
| DESCRIPTION | <p>This routine displays statistics about the available and allocated memory in its memory partition. It shows the number of bytes, the number of blocks, and the average block size in both free and allocated memory, and also the maximum block size of free memory. It also shows the number of blocks currently allocated and the average allocated block size.</p> <p>In addition, if <i>type</i> is 1, the routine displays a list of all the blocks in the free list of the specified partition.</p> |
| RETURNS | OK or ERROR. |
| SEE ALSO | VXWMemPart |

VXWMemPart::VXWMemPart()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | VXWMemPart::VXWMemPart() – create a memory partition (WFC Opt.) |
| SYNOPSIS | <pre>VXWMemPart (char * pool, unsigned poolSize)</pre> |
| DESCRIPTION | <p>This constructor creates a new memory partition containing a specified memory pool. Partitions can be created to manage any number of separate memory pools.</p> |
| NOTE | <p>The descriptor for the new partition is allocated out of the system memory partition (i.e., with <i>malloc()</i>).</p> |
| RETURNS | N/A. |
| SEE ALSO | VXWMemPart |

VXWModule::flags()

NAME *VXWModule::flags()* – get the flags associated with this module (WFC Opt.)

SYNOPSIS `int flags ()`

DESCRIPTION This routine returns the flags associated with its module.

RETURNS The option flags.

SEE ALSO *VXWModule*

VXWModule::info()

NAME *VXWModule::info()* – get information about object module (WFC Opt.)

SYNOPSIS `STATUS info
(
MODULE_INFO * pModuleInfo
) const`

DESCRIPTION This routine fills in a `MODULE_INFO` structure with information about the object module.

RETURNS OK or ERROR.

SEE ALSO *VXWModule*

VXWModule::name()

NAME *VXWModule::name()* – get the name associated with module (WFC Opt.)

SYNOPSIS `char * name ()`

DESCRIPTION This routine returns a pointer to the name associated with its module.

RETURNS A pointer to the module name.

SEE ALSO *VXWModule*

VXWModule::segFirst()

NAME *VXWModule::segFirst()* – find the first segment in module (WFC Opt.)

SYNOPSIS `SEGMENT_ID segFirst ()`

DESCRIPTION This routine returns information about the first segment of a module descriptor.

RETURNS A pointer to the segment ID.

SEE ALSO *VXWModule::segGet()*

VXWModule::segGet()

NAME *VXWModule::segGet()* – get (delete and return) the first segment from module (WFC Opt.)

SYNOPSIS `SEGMENT_ID segGet ()`

DESCRIPTION This routine returns information about the first segment of a module descriptor, and then deletes the segment from the module.

RETURNS A pointer to the segment ID, or NULL if the segment list is empty.

SEE ALSO *VXWModule::segFirst()*

VXWModule::segNext()

NAME *VXWModule::segNext()* – find the next segment in module (WFC Opt.)

SYNOPSIS `SEGMENT_ID segNext
(
 SEGMENT_ID segmentId
) const`

DESCRIPTION This routine returns the segment in the list immediately following *segmentId*.

RETURNS A pointer to the segment ID, or NULL if there is no next segment.

SEE ALSO **VXWModule**

VXWModule::VXWModule()

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | VXWModule::VXWModule() – build module object from module ID (WFC Opt.) |
| SYNOPSIS | <pre>VXWModule (MODULE_ID aModuleId)</pre> |
| DESCRIPTION | Use this constructor to manipulate a module that was not loaded using C++ interfaces. The argument <i>id</i> is the module identifier returned and used by the C interface to the VxWorks target-resident load facility. |
| RETURNS | N/A. |
| SEE ALSO | VXWModule , loadLib |

VXWModule::VXWModule()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | VXWModule::VXWModule() – load object module at memory addresses (WFC Opt.) |
| SYNOPSIS | <pre>VXWModule (int fd, int symFlag, char * *ppText, char * *ppData=0, char * *ppBss=0)</pre> |
| DESCRIPTION | This constructor reads an object module from <i>fd</i> , and loads the code, data, and BSS segments at the specified load addresses in memory set aside by the caller using VXWMemPart::alloc() , or in the system memory partition as described below. The module is properly relocated according to the relocation commands in the file. Unresolved externals will be linked to symbols found in the system symbol table. Symbols in the module being loaded can optionally be added to the system symbol table. |

LINKING UNRESOLVED EXTERNALS

As the module is loaded, any unresolved external references are resolved by looking up the missing symbols in the the system symbol table. If found, those references are

correctly linked to the new module. If unresolved external references cannot be found in the system symbol table, then an error message ("undefined symbol: ...") is printed for the symbol, but the loading/linking continues. In this case, NULL is returned after the module is loaded.

ADDING SYMBOLS TO THE SYMBOL TABLE

The symbols defined in the module to be loaded may be optionally added to the target-resident system symbol table, depending on the value of *symFlag*:

LOAD_NO_SYMBOLS

add no symbols to the system symbol table

LOAD_LOCAL_SYMBOLS

add only local symbols to the system symbol table

LOAD_GLOBAL_SYMBOLS

add only external symbols to the system symbol table

LOAD_ALL_SYMBOLS

add both local and external symbols to the system symbol table

HIDDEN_MODULE

do not display the module via *moduleShow()*.

In addition, the following symbols are added to the symbol table to indicate the start of each segment: *file_text*, *file_data*, and *file_bss*, where *file* is the name associated with the fd.

RELOCATION

The relocation commands in the object module are used to relocate the text, data, and BSS segments of the module. The location of each segment can be specified explicitly, or left unspecified in which case memory is allocated for the segment from the system memory partition. This is determined by the parameters *ppText*, *ppData*, and *ppBss*, each of which can have the following values:

NULL

no load address is specified, none will be returned;

A pointer to LD_NO_ADDRESS

no load address is specified, the return address is referenced by the pointer;

A pointer to an address

the load address is specified.

The *ppText*, *ppData*, and *ppBss* parameters specify where to load the text, data, and bss sections respectively. Each of these parameters is a pointer to a pointer; for example, ***ppText* gives the address where the text segment is to begin.

For any of the three parameters, there are two ways to request that new memory be allocated, rather than specifying the section's starting address: you can either specify the parameter itself as NULL, or you can write the constant LD_NO_ADDRESS in place of an address. In the second case, this constructor replaces the LD_NO_ADDRESS value with the address actually used for each section (that is, it records the address at **ppText*, **ppData*, or **ppBss*).

The double indirection not only permits reporting the addresses actually used, but also allows you to specify loading a segment at the beginning of memory, since the following cases can be distinguished:

- (1) Allocate memory for a section (text in this example): `ppText == NULL`
- (2) Begin a section at address zero (the text section, below): `*ppText == 0`

Note that `loadModule()` is equivalent to this routine if all three of the segment-address parameters are set to `NULL`.

COMMON Some host compiler/linker combinations internally use another storage class known as *common*. In the C language, uninitialized global variables are eventually put in the BSS segment. However, in partially linked object modules they are flagged internally as common and the static linker on the host resolves these and places them in BSS as a final step in creating a fully linked object module. However, the VxWorks target-resident dynamic loader is most often used to load partially linked object modules. When the VxWorks loader encounters a variable labeled as common, memory for the variable is allocated, and the variable is entered in the system symbol table (if specified) at that address. Note that most static loaders have an option that forces resolution of the common storage while leaving the module relocatable.

RETURNS N/A.

SEE ALSO `VXWModule`, *VxWorks Programmer's Guide: C++ Development*

VXWModule::VXWModule()

NAME `VXWModule::VXWModule()` – load an object module into memory (WFC Opt.)

SYNOPSIS

```
VXWModule
(
    int fd,
    int symFlag
)
```

DESCRIPTION This constructor loads an object module from the file descriptor `fd`, and places the code, data, and BSS into memory allocated from the system memory pool.

RETURNS N/A.

SEE ALSO `VXWModule`

VXWModule::VXWModule()

NAME VXWModule::VXWModule() – create and initialize an object module (WFC Opt.)

SYNOPSIS

```
VXWModule
(
    char * name,
    int   format,
    int   flags
)
```

DESCRIPTION This constructor creates an object module descriptor. It is usually called from another constructor.

The arguments specify the name of the object module file, the object module format, and a collection of options *flags*.

Space for the new module is dynamically allocated.

RETURNS N/A.

SEE ALSO VXWModule

VXWModule::~VXWModule()

NAME VXWModule::~VXWModule() – unload an object module (WFC Opt.)

SYNOPSIS

```
~VXWModule ()
```

DESCRIPTION This destructor unloads the object module from the target system. For a.out and ECOFF format modules, unloading does the following:

- (1) It frees the space allocated for text, data, and BSS segments, unless *VXWModule::VXWModule()* was called with specific addresses, in which case the application is responsible for freeing space.
- (2) It removes all symbols associated with the object module from the system symbol table.
- (3) It removes the module descriptor from the module list.

For other modules of other formats, unloading has similar effects.

Unloading modules with this interface has no effect on breakpoints in other modules.

RETURNS N/A.

SEE ALSO VXWModule

VXWMSem::giveForce()

NAME VXWMSem::giveForce() – give mutex semaphore without restrictions (WFC Opt.)

SYNOPSIS STATUS giveForce ()

DESCRIPTION This routine gives a mutual-exclusion semaphore, regardless of semaphore ownership. It is intended as a debugging aid only.

The routine is particularly useful when a task dies while holding some mutual-exclusion semaphore, because the semaphore can be resurrected. The routine gives the semaphore to the next task in the pend queue, or makes the semaphore full if no tasks are pending. In effect, execution continues as if the task owning the semaphore had actually given the semaphore.

CAVEATS Use this routine should only as a debugging aid, when the condition of the semaphore is known.

RETURNS OK.

SEE ALSO VXWSem::give()

VXWMSem::VXWMSem()

NAME VXWMSem::VXWMSem() – create and initialize a mutex semaphore (WFC Opt.)

SYNOPSIS VXWMSem
(
int opts
)

DESCRIPTION This routine allocates and initializes a mutual-exclusion semaphore. The semaphore state is initialized to full.

Semaphore options include the following:

VXWMSem::VXWMSem()

SEM_Q_PRIORITY

Queue pending tasks on the basis of their priority.

SEM_Q_FIFO

Queue pending tasks on a first-in-first-out basis.

SEM_DELETE_SAFE

Protect a task that owns the semaphore from unexpected deletion. This option enables an implicit *taskSafe()* for each *VXWSem::take()*, and an implicit *taskUnsafe()* for each *VXWSem::give()*.

SEM_INVERSION_SAFE

Protect the system from priority inversion. With this option, the task owning the semaphore executes at the highest priority of the tasks pending on the semaphore, if that is higher than its current priority. This option must be accompanied by the **SEM_Q_PRIORITY** queuing mode.

Mutual-exclusion semaphores offer convenient options suited for situations that require mutually exclusive access to resources. Typical applications include sharing devices and protecting data structures. Mutual-exclusion semaphores are used by many higher-level VxWorks facilities.

The mutual-exclusion semaphore is a specialized version of the binary semaphore, designed to address issues inherent in mutual exclusion, such as recursive access to resources, priority inversion, and deletion safety. The fundamental behavior of the mutual-exclusion semaphore is identical to the binary semaphore as described for *VXWBSem::VXWBSem()*, except for the following restrictions:

- It can only be used for mutual exclusion.
- It can only be given by the task that took it.
- It may not be taken or given from interrupt level.
- The *VXWSem::flush()* operation is illegal.

These last two operations have no meaning in mutual-exclusion situations.

RECURSIVE RESOURCE ACCESS

A special feature of the mutual-exclusion semaphore is that it may be taken "recursively;" that is, it can be taken more than once by the task that owns it before finally being released. Recursion is useful for a set of routines that need mutually exclusive access to a resource, but may need to call each other.

Recursion is possible because the system keeps track of which task currently owns a mutual-exclusion semaphore. Before being released, a mutual-exclusion semaphore taken recursively must be given the same number of times it has been taken; this is tracked by means of a count which increments with each *VXWSem::take()* and decrements with each *VXWSem::give()*.

PRIORITY-INVERSION SAFETY

If the option `SEM_INVERSION_SAFE` is selected, the library adopts a priority-inheritance protocol to resolve potential occurrences of "priority inversion," a problem stemming from the use semaphores for mutual exclusion. Priority inversion arises when a higher-priority task is forced to wait an indefinite period of time for the completion of a lower-priority task.

Consider the following scenario: T1, T2, and T3 are tasks of high, medium, and low priority, respectively. T3 has acquired some resource by taking its associated semaphore. When T1 preempts T3 and contends for the resource by taking the same semaphore, it becomes blocked. If we could be assured that T1 would be blocked no longer than the time it normally takes T3 to finish with the resource, the situation would not be problematic. However, the low-priority task is vulnerable to preemption by medium-priority tasks; a preempting task, T2, could inhibit T3 from relinquishing the resource. This condition could persist, blocking T1 for an indefinite period of time.

The priority-inheritance protocol solves the problem of priority inversion by elevating the priority of T3 to the priority of T1 during the time T1 is blocked on T3. This protects T3, and indirectly T1, from preemption by T2. Stated more generally, the priority-inheritance protocol assures that a task which owns a resource executes at the priority of the highest priority task blocked on that resource. When execution is complete, the task gives up the resource and returns to its normal, or standard, priority. Hence, the "inheriting" task is protected from preemption by any intermediate-priority tasks.

The priority-inheritance protocol also takes into consideration a task's ownership of more than one mutual-exclusion semaphore at a time. Such a task will execute at the priority of the highest priority task blocked on any of the resources it owns. The task returns to its normal priority only after relinquishing all of its mutual-exclusion semaphores that have the inversion-safety option enabled.

SEMAPHORE DELETION

The `VXWSem::~~VXWSem()` destructor terminates a semaphore and deallocates any associated memory. The deletion of a semaphore unblocks tasks pended on that semaphore; the routines which were pended return `ERROR`. Take special care when deleting mutual-exclusion semaphores to avoid deleting a semaphore out from under a task that already owns (has taken) that semaphore. Applications should adopt the protocol of only deleting semaphores that the deleting task owns.

TASK-DELETION SAFETY

If the option `SEM_DELETE_SAFE` is selected, the task owning the semaphore is protected from deletion as long as it owns the semaphore. This solves another problem endemic to mutual exclusion. Deleting a task executing in a critical region can be catastrophic. The resource could be left in a corrupted state and the semaphore guarding the resource would be unavailable, effectively shutting off all access to the resource.

As discussed in `taskLib`, the primitives `taskSafe()` and `taskUnsafe()` offer one solution, but as this type of protection goes hand in hand with mutual exclusion, the

VXWMsgQ::info()

mutual-exclusion semaphore provides the option `SEM_DELETE_SAFE`, which enables an implicit `taskSafe()` with each `VXWSem::take()`, and a `taskUnsafe()` with each `VXWSem::give()`. This convenience is also more efficient, as the resulting code requires fewer entrances to the kernel.

- CAVEATS** There is no mechanism to give back or reclaim semaphores automatically when tasks are suspended or deleted. Such a mechanism, though desirable, is not currently feasible. Without explicit knowledge of the state of the guarded resource or region, reckless automatic reclamation of a semaphore could leave the resource in a partial state. Thus if a task ceases execution unexpectedly, as with a bus error, currently owned semaphores will not be given back, effectively leaving a resource permanently unavailable. The `SEM_DELETE_SAFE` option partially protects an application, to the extent that unexpected deletions will be deferred until the resource is released.
- RETURNS** N/A
- SEE ALSO** `VXWSem`, `taskSafe()`, `taskUnsafe()`

VXWMsgQ::info()

NAME `VXWMsgQ::info()` – get information about message queue (WFC Opt.)

SYNOPSIS

```
STATUS info
(
    MSG_Q_INFO * pInfo
) const
```

DESCRIPTION This routine gets information about the state and contents of its message queue. The parameter `pInfo` is a pointer to a structure of type `MSG_Q_INFO` defined in `msgQLib.h` as follows:

```
typedef struct          /* MSG_Q_INFO */
{
    int    numMsgs;      /* OUT: number of messages queued */
    int    numTasks;     /* OUT: number of tasks waiting on msg q */
    int    sendTimeouts; /* OUT: count of send timeouts */
    int    rcvTimeouts;  /* OUT: count of receive timeouts */
    int    options;      /* OUT: options with which msg q was created */
    int    maxMsgs;      /* OUT: max messages that can be queued */
    int    maxMsgLength; /* OUT: max byte length of each message */
    int    taskIdListMax; /* IN: max tasks to fill in taskIdList */
    int *  taskIdList;   /* PTR: array of task IDs waiting on msg q */
    int    msgListMax;   /* IN: max msgs to fill in msg lists */
}
```

```

char ** msgPtrList;      /* PTR: array of msg ptrs queued to msg q  */
int *  msgLenList;      /* PTR: array of lengths of msgs          */
} MSG_Q_INFO;

```

If the message queue is empty, there may be tasks blocked on receiving. If the message queue is full, there may be tasks blocked on sending. This can be determined as follows:

- If *numMsgs* is 0, then *numTasks* indicates the number of tasks blocked on receiving.
- If *numMsgs* is equal to *maxMsgs*, then *numTasks* is the number of tasks blocked on sending.
- If *numMsgs* is greater than 0 but less than *maxMsgs*, then *numTasks* will be 0.

A list of pointers to the messages queued and their lengths can be obtained by setting *msgPtrList* and *msgLenList* to the addresses of arrays to receive the respective lists, and setting *msgListMax* to the maximum number of elements in those arrays. If either list pointer is NULL, no data is returned for that array.

No more than *msgListMax* message pointers and lengths are returned, although *numMsgs* is always returned with the actual number of messages queued.

For example, if the caller supplies a *msgPtrList* and *msgLenList* with room for 10 messages and sets *msgListMax* to 10, but there are 20 messages queued, then the pointers and lengths of the first 10 messages in the queue are returned in *msgPtrList* and *msgLenList*, but *numMsgs* is returned with the value 20.

A list of the task IDs of tasks blocked on the message queue can be obtained by setting *taskIdList* to the address of an array to receive the list, and setting *taskIdListMax* to the maximum number of elements in that array. If *taskIdList* is NULL, then no task IDs are returned. No more than *taskIdListMax* task IDs are returned, although *numTasks* is always returned with the actual number of tasks blocked.

For example, if the caller supplies a *taskIdList* with room for 10 task IDs and sets *taskIdListMax* to 10, but there are 20 tasks blocked on the message queue, then the IDs of the first 10 tasks in the blocked queue are returned in *taskIdList*, but *numTasks* is returned with the value 20.

Note that the tasks returned in *taskIdList* may be blocked for either send or receive. As noted above this can be determined by examining *numMsgs*. The variables *sendTimeouts* and *recvTimeouts* are the counts of the number of times *VXWMsgQ::send()* and *VXWMsgQ::receive()* (or their equivalents in other language bindings) respectively returned with a timeout.

The variables *options*, *maxMsgs*, and *maxMsgLength* are the parameters with which the message queue was created.

WARNING

The information returned by this routine is not static and may be obsolete by the time it is examined. In particular, the lists of task IDs and/or message pointers may no longer be valid. However, the information is obtained atomically, thus it is an accurate snapshot of

VXWMsgQ::numMsgs()

the state of the message queue at the time of the call. This information is generally used for debugging purposes only.

- WARNING** The current implementation of this routine locks out interrupts while obtaining the information. This can compromise the overall interrupt latency of the system. Generally this routine is used for debugging purposes only.
- RETURNS** OK or ERROR.
- SEE ALSO** **VXWMsgQ**

VXWMsgQ::numMsgs()

- NAME** ***VXWMsgQ::numMsgs()*** – report the number of messages queued (WFC Opt.)
- SYNOPSIS** `int numMsgs ()`
- DESCRIPTION** This routine returns the number of messages currently queued to the message queue.
- RETURNS** The number of messages queued, or ERROR.
- ERRNO** **S_objLib_OBJ_ID_ERROR**
– *msgQId* is invalid.
- SEE ALSO** **VXWMsgQ**

VXWMsgQ::receive()

- NAME** ***VXWMsgQ::receive()*** – receive a message from message queue (WFC Opt.)
- SYNOPSIS** `int receive
(
 char * buffer,
 UINT nBytes,
 int timeout
)`

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | <p>This routine receives a message from its message queue. The received message is copied into the specified <i>buffer</i>, which is <i>nBytes</i> in length. If the message is longer than <i>nBytes</i>, the remainder of the message is discarded (no error indication is returned).</p> <p>The <i>timeout</i> parameter specifies the number of ticks to wait for a message to be sent to the queue, if no message is available when VXWMsgQ::receive() is called. The <i>timeout</i> parameter can also have the following special values:</p> <p>NO_WAIT return immediately, even if the message has not been sent.</p> <p>WAIT_FOREVER never time out.</p> |
| WARNING | This routine must not be called by interrupt service routines. |
| RETURNS | The number of bytes copied to <i>buffer</i> , or ERROR. |
| ERRNO | <p>S_objLib_OBJ_DELETED – the message queue was deleted while waiting to receive a message.</p> <p>S_objLib_OBJ_UNAVAILABLE – <i>timeout</i> is set to NO_WAIT, and no messages are available.</p> <p>S_objLib_OBJ_TIMEOUT – no messages were received in <i>timeout</i> ticks.</p> <p>S_msgQLib_INVALID_MSG_LENGTH – <i>nBytes</i> is less than 0.</p> |
| SEE ALSO | VXWMsgQ |

VXWMsgQ::send()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | VXWMsgQ::send() – send a message to message queue (WFC Opt.) |
| SYNOPSIS | <pre> STATUS send (char * buffer, UINT nBytes, int timeout, int pri) </pre> |
| DESCRIPTION | This routine sends the message in <i>buffer</i> of length <i>nBytes</i> to its message queue. If any tasks are already waiting to receive messages on the queue, the message is immediately |

delivered to the first waiting task. If no task is waiting to receive messages, the message is saved in the message queue.

The *timeout* parameter specifies the number of ticks to wait for free space if the message queue is full. The *timeout* parameter can also have the following special values:

NO_WAIT

return immediately, even if the message has not been sent.

WAIT_FOREVER

never time out.

The *pri* parameter specifies the priority of the message being sent. The possible values are:

MSG_PRI_NORMAL

normal priority; add the message to the tail of the list of queued messages.

MSG_PRI_URGENT

urgent priority; add the message to the head of the list of queued messages.

USE BY INTERRUPT SERVICE ROUTINES

This routine can be called by interrupt service routines as well as by tasks. This is one of the primary means of communication between an interrupt service routine and a task. When called from an interrupt service routine, *timeout* must be **NO_WAIT**.

RETURNS

OK or ERROR.

ERRNO

S_objLib_OBJ_DELETED

– the message queue was deleted while waiting to a send message.

S_objLib_OBJ_UNAVAILABLE

– *timeout* is set to **NO_WAIT**, and the queue is full.

S_objLib_OBJ_TIMEOUT

– the queue is full for *timeout* ticks.

S_msgQLib_INVALID_MSG_LENGTH

– *nBytes* is larger than the *maxMsgLength* set for the message queue.

S_msgQLib_NON_ZERO_TIMEOUT_AT_INT_LEVEL

– called from an ISR, with *timeout* not set to **NO_WAIT**.

SEE ALSO

VXWMsgQ

VXWMsgQ::show()

NAME VXWMsgQ::show() – show information about a message queue (WFC Opt.)

SYNOPSIS

```
STATUS show
(
  int level
) const
```

DESCRIPTION This routine displays the state and optionally the contents of a message queue.

A summary of the state of the message queue is displayed as follows:

```
Message Queue Id   : 0x3f8c20
Task Queuing       : FIFO
Message Byte Len   : 150
Messages Max       : 50
Messages Queued    : 0
Receivers Blocked  : 1
Send timeouts      : 0
Receive timeouts   : 0
```

If *level* is 1, more detailed information is displayed. If messages are queued, they are displayed as follows:

```
Messages queued:
#  address length value
1 0x123eb204 4 0x00000001 0x12345678
```

If tasks are blocked on the queue, they are displayed as follows:

```
Receivers blocked:
NAME      TID    PRI  DELAY
-----
tExcTask  3fd678  0    21
```

RETURNS OK or ERROR.

SEE ALSO VXWMsgQ

VXWMsgQ::VXWMsgQ()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | VXWMsgQ::VXWMsgQ() – create and initialize a message queue (WFC Opt.) |
| SYNOPSIS | <pre>VXWMsgQ (int maxMsgs, int maxMsgLen, int opts)</pre> |
| DESCRIPTION | <p>This constructor creates a message queue capable of holding up to <i>maxMsgs</i> messages, each up to <i>maxMsgLen</i> bytes long. The queue can be created with the following options specified as <i>opts</i>:</p> <p>MSG_Q_FIFO queue pended tasks in FIFO order.</p> <p>MSG_Q_PRIORITY queue pended tasks in priority order.</p> |
| RETURNS | N/A. |
| ERRNO | <p>S_memLib_NOT_ENOUGH_MEMORY – unable to allocate memory for message queue and message buffers.</p> <p>S_intLib_NOT_ISR_CALLABLE – called from an interrupt service routine.</p> |
| SEE ALSO | VXWMsgQ, vxwSmLib |

VXWMsgQ::VXWMsgQ()

| | |
|-----------------|--------------------------------------------------------------------|
| NAME | VXWMsgQ::VXWMsgQ() – build message-queue object from ID (WFC Opt.) |
| SYNOPSIS | <pre>VXWMsgQ (MSG_Q_ID id)</pre> |

DESCRIPTION Use this constructor to manipulate a message queue that was not created using C++ interfaces. The argument *id* is the message-queue identifier returned and used by the C interface to the VxWorks message queue facility.

RETURNS N/A.

SEE ALSO **VXWMsgQ**, **msgQLib**

VXWMsgQ::~VXWMsgQ()

NAME ***VXWMsgQ::~VXWMsgQ()*** – delete message queue (WFC Opt.)

SYNOPSIS `virtual ~VXWMsgQ ()`

DESCRIPTION This destructor deletes a message queue. Any task blocked on either a ***VXWMsgQ::send()*** or ***VXWMsgQ::receive()*** is unblocked and receives an error from the call with **errno** set to **S_objLib_OBJECT_DELETED**.

RETURNS N/A.

ERRNO **S_objLib_OBJ_ID_ERROR**
 – *msgQId* is invalid.

S_intLib_NOT_ISR_CALLABLE
 – called from an interrupt service routine.

SEE ALSO **VXWMsgQ**

VXWRingBuf::flush()

NAME ***VXWRingBuf::flush()*** – make ring buffer empty (WFC Opt.)

SYNOPSIS `void flush ()`

DESCRIPTION This routine initializes the ring buffer to be empty. Any data in the buffer is lost.

RETURNS N/A

SEE ALSO **VXWRingBuf**

VXWRingBuf::freeBytes()

NAME VXWRingBuf::freeBytes() – determine the number of free bytes in ring buffer (WFC Opt.)

SYNOPSIS `int freeBytes ()`

DESCRIPTION This routine determines the number of bytes currently unused in the ring buffer.

RETURNS The number of unused bytes in the ring buffer.

SEE ALSO VXWRingBuf

VXWRingBuf::get()

NAME VXWRingBuf::get() – get characters from ring buffer (WFC Opt.)

SYNOPSIS `int get
(
char * buffer,
int maxbytes
)`

DESCRIPTION This routine copies bytes from the ring buffer into *buffer*. It copies as many bytes as are available in the ring, up to *maxbytes*. The bytes copied are then removed from the ring.

RETURNS The number of bytes actually received from the ring buffer; it may be zero if the ring buffer is empty at the time of the call.

SEE ALSO VXWRingBuf

VXWRingBuf::isEmpty()

NAME VXWRingBuf::isEmpty() – test whether ring buffer is empty (WFC Opt.)

SYNOPSIS `BOOL isEmpty ()`

DESCRIPTION This routine reports on whether the ring buffer is empty.

RETURNS TRUE if empty, FALSE if not.

SEE ALSO VXWRingBuf

VXWRingBuf::isFull()

NAME *VXWRingBuf::isFull()* – test whether ring buffer is full (no more room) (WFC Opt.)

SYNOPSIS `BOOL isFull ()`

DESCRIPTION This routine reports on whether the ring buffer is completely full.

RETURNS TRUE if full, FALSE if not.

SEE ALSO VXWRingBuf

VXWRingBuf::moveAhead()

NAME *VXWRingBuf::moveAhead()* – advance ring pointer by *n* bytes (WFC Opt.)

SYNOPSIS `void moveAhead
(
 int n
)`

DESCRIPTION This routine advances the ring buffer input pointer by *n* bytes. This makes *n* bytes available in the ring buffer, after having been written ahead in the ring buffer with *VXWRingBuf::putAhead()*.

RETURNS N/A

SEE ALSO VXWRingBuf

VXWRingBuf::nBytes()

NAME *VXWRingBuf::nBytes()* – determine the number of bytes in ring buffer (WFC Opt.)

SYNOPSIS `int nBytes ()`

DESCRIPTION This routine determines the number of bytes currently in the ring buffer.

RETURNS The number of bytes filled in the ring buffer.

SEE ALSO **VXWRingBuf**

VXWRingBuf::put()

NAME *VXWRingBuf::put()* – put bytes into ring buffer (WFC Opt.)

SYNOPSIS `int put
(
 char * buffer,
 int nBytes
)`

DESCRIPTION This routine puts bytes from *buffer* into the ring buffer. The specified number of bytes is put into the ring, up to the number of bytes available in the ring.

RETURNS The number of bytes actually put into the ring buffer; it may be less than number requested, even zero, if there is insufficient room in the ring buffer at the time of the call.

SEE ALSO **VXWRingBuf**

VXWRingBuf::putAhead()

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>VXWRingBuf::putAhead()</i> – put a byte ahead in a ring buffer without moving ring pointers (WFC Opt.) |
| SYNOPSIS | <pre>void putAhead (char byte, int offset)</pre> |
| DESCRIPTION | <p>This routine writes a byte into the ring, but does not move the ring buffer pointers. Thus the byte is not yet be available to <i>VXWRingBuf::get()</i> calls. The byte is written <i>offset</i> bytes ahead of the next input location in the ring. Thus, an offset of 0 puts the byte in the same position as <i>VXWRingBuf::put()</i> would put a byte, except that the input pointer is not updated.</p> <p>Bytes written ahead in the ring buffer with this routine can be made available all at once by subsequently moving the ring buffer pointers with the routine <i>VXWRingBuf::moveAhead()</i>.</p> <p>Before calling <i>VXWRingBuf::putAhead()</i>, the caller must verify that at least <i>offset</i> + 1 bytes are available in the ring buffer.</p> |
| RETURNS | N/A |
| SEE ALSO | <i>VXWRingBuf</i> |

VXWRingBuf::VXWRingBuf()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>VXWRingBuf::VXWRingBuf()</i> – create an empty ring buffer (WFC Opt.) |
| SYNOPSIS | <pre>VXWRingBuf (int nbytes)</pre> |
| DESCRIPTION | This constructor creates a ring buffer of size <i>nbytes</i> , and initializes it. Memory for the buffer is allocated from the system memory partition. |
| RETURNS | N/A. |
| SEE ALSO | <i>VXWRingBuf</i> |

VXWRingBuf::VXWRingBuf()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | VXWRingBuf::VXWRingBuf() – build ring-buffer object from existing ID (WFC Opt.) |
| SYNOPSIS | <pre>VXWRingBuf (RING_ID aRingId)</pre> |
| DESCRIPTION | Use this constructor to build a ring-buffer object from an existing ring buffer. This permits you to use the C++ ring-buffer interfaces even if the ring buffer itself was created by a routine written in C. |
| RETURNS | N/A. |
| SEE ALSO | VXWRingBuf , rngLib |

VXWRingBuf::~VXWRingBuf()

| | |
|--------------------|------------------------------------------------------------------------------------------------------------|
| NAME | VXWRingBuf::~VXWRingBuf() – delete ring buffer (WFC Opt.) |
| SYNOPSIS | <pre>~VXWRingBuf ()</pre> |
| DESCRIPTION | This destructor deletes a specified ring buffer. Any data in the buffer at the time it is deleted is lost. |
| RETURNS | N/A |
| SEE ALSO | VXWRingBuf |

VXWSem::flush()

| | |
|-----------------|-------------------------------------------------------------------------------|
| NAME | VXWSem::flush() – unblock every task pended on a semaphore (WFC Opt.) |
| SYNOPSIS | <pre>STATUS flush ()</pre> |

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | This routine atomically unblocks all tasks pended on a specified semaphore; that is, all tasks are unblocked before any is allowed to run. The state of the underlying semaphore is unchanged. All pended tasks enter the ready queue before having a chance to execute. The flush operation is useful as a means of broadcast in synchronization applications. Its use is illegal for mutual-exclusion semaphores created with <i>VXWMSem::VXWMSem()</i> . |
| RETURNS | OK, or ERROR if the operation is not supported. |
| SEE ALSO | <i>VXWSem</i> , <i>VXWCsem::VXWCsem()</i> , <i>VXWBSem::VXWBsem()</i> , <i>VXWMSem::VXWMsem()</i> , <i>VxWorks Programmer's Guide: Basic OS</i> |

VXWSem::give()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>VXWSem::give()</i> – give a semaphore (WFC Opt.) |
| SYNOPSIS | <code>STATUS give ()</code> |
| DESCRIPTION | This routine performs the give operation on a specified semaphore. Depending on the type of semaphore, the state of the semaphore and of the pending tasks may be affected. The behavior of <i>VXWSem::give()</i> is discussed fully in the constructor description for the specific semaphore type being used. |
| RETURNS | OK. |
| SEE ALSO | <i>VXWSem</i> , <i>VXWCsem::VXWCsem()</i> , <i>VXWBSem::VXWBsem()</i> , <i>VXWMSem::VXWMsem()</i> , <i>VxWorks Programmer's Guide: Basic OS</i> |

VXWSem::id()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>VXWSem::id()</i> – reveal underlying semaphore ID (WFC Opt.) |
| SYNOPSIS | <code>SEM_ID id ()</code> |
| DESCRIPTION | This routine returns the semaphore ID corresponding to a semaphore object. The semaphore ID is used by the C interface to VxWorks semaphores. |
| RETURNS | Semaphore ID. |
| SEE ALSO | <i>VXWSem</i> , <i>semLib</i> |

VXWSem::info()

VXWSem::info()

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | VXWSem::info() – get a list of task IDs that are blocked on a semaphore (WFC Opt.) |
| SYNOPSIS | <pre> STATUS info (int idList[], int maxTasks) const </pre> |
| DESCRIPTION | This routine reports the tasks blocked on a specified semaphore. Up to <i>maxTasks</i> task IDs are copied to the array specified by <i>idList</i> . The array is unordered. |
| WARNING | There is no guarantee that all listed tasks are still valid or that new tasks have not been blocked by the time VXWSem::info() returns. |
| RETURNS | The number of blocked tasks placed in <i>idList</i> . |
| SEE ALSO | VXWSem |

VXWSem::show()

| | |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | VXWSem::show() – show information about a semaphore (WFC Opt.) |
| SYNOPSIS | <pre> STATUS show (int level) const </pre> |
| DESCRIPTION | <p>This routine displays (on standard output) the state and optionally the pending tasks of a semaphore.</p> <p>A summary of the state of the semaphore is displayed as follows:</p> <pre> Semaphore Id : 0x585f2 Semaphore Type : BINARY Task Queuing : PRIORITY Pended Tasks : 1 State : EMPTY {Count if COUNTING, Owner if MUTEX} </pre> <p>If <i>level</i> is 1, more detailed information is displayed. If tasks are blocked on the queue, they are displayed in the order in which they will unblock, as follows:</p> |

| NAME | TID | PRI | DELAY |
|----------|--------|-----|-------|
| tExcTask | 3fd678 | 0 | 21 |
| tLogTask | 3f8ac0 | 0 | 611 |

RETURNS OK or ERROR.

SEE ALSO VXWSem

VXWSem::take()

NAME VXWSem::take() – take a semaphore (WFC Opt.)

SYNOPSIS

```
STATUS take
(
    int timeout
)
```

DESCRIPTION This routine performs the take operation on a specified semaphore. Depending on the type of semaphore, the state of the semaphore and the calling task may be affected. The behavior of *VXWSem::take()* is discussed fully in the constructor description for the specific semaphore type being used.

A timeout in ticks may be specified. If a task times out, *VXWSem::take()* returns ERROR. Timeouts of `WAIT_FOREVER` and `NO_WAIT` indicate to wait indefinitely or not to wait at all.

When *VXWSem::take()* returns due to timeout, it sets the `errno` to `S_objLib_OBJ_TIMEOUT` (defined in `objLib.h`).

The *VXWSem::take()* routine must not be called from interrupt service routines.

RETURNS OK, or ERROR if the task timed out.

SEE ALSO *VXWSem*, *VXWCSem::VXWCsem()*, *VXWBSem::VXWBsem()*, *VXWMSem::VXWMsem()*, *VxWorks Programmer's Guide: Basic OS*

VXWSem::VXWSem()

VXWSem::VXWSem()

| | |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | VXWSem::VXWSem() – build semaphore object from semaphore ID (WFC Opt.) |
| SYNOPSIS | <pre>VXWSem (SEM_ID id)</pre> |
| DESCRIPTION | Use this constructor to manipulate a semaphore that was not created using C++ interfaces. The argument <i>id</i> is the semaphore identifier returned and used by the C interface to the VxWorks semaphore facility. |
| RETURNS | N/A |
| SEE ALSO | VXWSem , semLib |

VXWSem::~VXWSem()

| | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | VXWSem::~VXWSem() – delete a semaphore (WFC Opt.) |
| SYNOPSIS | <pre>virtual ~VXWSem ()</pre> |
| DESCRIPTION | This destructor terminates and deallocates any memory associated with a specified semaphore. Any pending tasks unblock and return ERROR. |
| WARNING | Take care when deleting semaphores, particularly those used for mutual exclusion, to avoid deleting a semaphore out from under a task that already has taken (owns) that semaphore. Applications should adopt the protocol of only deleting semaphores that the deleting task has successfully taken. |
| RETURNS | N/A |
| SEE ALSO | VXWSem , <i>VxWorks Programmer's Guide: Basic OS</i> |

VXWsmName::nameGet()

| | |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | VXWsmName::nameGet() – get name and type of a shared memory object (VxMP Opt.) |
| SYNOPSIS | <pre> STATUS nameGet (char * name, int * pType, int waitType) </pre> |
| DESCRIPTION | <p>This routine searches the shared memory name database for an object matching this VXWsmName instance. If the object is found, its name and type are copied to the addresses pointed to by <i>name</i> and <i>pType</i>. The value of <i>waitType</i> can be one of the following:</p> <p>NO_WAIT (0) The call returns immediately, even if the object value is not in the database</p> <p>WAIT_FOREVER (-1) The call returns only when the object value is available in the database.</p> |
| AVAILABILITY | This routine depends on the unbundled shared memory objects support option, VxMP. |
| RETURNS | OK, or ERROR if <i>value</i> is not found or if the wait type is invalid. |
| ERRNO | S_smNameLib_NOT_INITIALIZED S_smNameLib_VALUE_NOT_FOUND S_smNameLib_INVALID_WAIT_TYPE S_smObjLib_LOCK_TIMEOUT |
| SEE ALSO | VXWsmName |

VXWsmName::nameGet()

| | |
|-----------------|------------------------------------------------------------------------------------------|
| NAME | VXWsmName::nameGet() – get name of a shared memory object (VxMP Opt.) (WFC Opt.) |
| SYNOPSIS | <pre> STATUS nameGet (char * name, int waitType) </pre> |

VXWsmName::nameSet()

| | |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DESCRIPTION | This routine searches the shared memory name database for an object matching this VXWsmName instance. If the object is found, its name is copied to the address pointed to by <i>name</i> . The value of <i>waitType</i> can be one of the following: NO_WAIT (0) The call returns immediately, even if the object value is not in the database WAIT_FOREVER (-1) The call returns only when the object value is available in the database. |
| AVAILABILITY | This routine depends on the unbundled shared memory objects support option, VxMP. |
| RETURNS | OK, or ERROR if <i>value</i> is not found or if the wait type is invalid. |
| ERRNO | S_smNameLib_NOT_INITIALIZED S_smNameLib_VALUE_NOT_FOUND S_smNameLib_INVALID_WAIT_TYPE S_smObjLib_LOCK_TIMEOUT |
| SEE ALSO | VXWsmName |

VXWsmName::nameSet()

| | |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | VXWsmName::nameSet() – define a name string in the shared-memory name database (VxMP Opt.) (WFC Opt.) |
| SYNOPSIS | <pre>virtual STATUS nameSet (char * name) = 0</pre> |
| DESCRIPTION | <p>This routine adds a name of the type appropriate for each derived class to the database of memory object names.</p> <p>The <i>name</i> parameter is an arbitrary null-terminated string with a maximum of 20 characters, including EOS.</p> <p>A name can be entered only once in the database, but there can be more than one name associated with an object ID.</p> |
| AVAILABILITY | This routine depends on the unbundled shared memory objects support option, VxMP. |
| RETURNS | OK, or ERROR if there is insufficient memory for <i>name</i> to be allocated, if <i>name</i> is already in the database, or if the database is already full. |

ERRNO *S_smNameLib_NOT_INITIALIZED*
S_smNameLib_NAME_TOO_LONG
S_smNameLib_NAME_ALREADY_EXIST
S_smNameLib_DATABASE_FULL
S_smObjLib_LOCK_TIMEOUT

SEE ALSO *VXWSmName*

VXWSmName::~~VXWSmName()

NAME *VXWSmName::~~VXWSmName()* – remove an object from the shared memory objects name database (VxMP Opt.) (WFC Opt.)

SYNOPSIS `virtual ~VXWSmName ()`

DESCRIPTION This routine removes an object from the shared memory objects name database.

AVAILABILITY This routine depends on code distributed as a component of the unbundled shared memory objects support option, VxMP.

RETURNS OK, or ERROR if the database is not initialized, or the name-database lock times out.

ERRNO *S_smNameLib_NOT_INITIALIZED*
S_smObjLib_LOCK_TIMEOUT

SEE ALSO *VXWSmName*

VXWSymTab::add()

NAME *VXWSymTab::add()* – create and add a symbol to a symbol table, including a group number (WFC Opt.)

SYNOPSIS `STATUS add`
`(`
`char * name,`
`char * value,`
`SYM_TYPE type,`
`UINT16 group`
`)`

VXWSymTab::each()

- DESCRIPTION** This routine allocates a symbol *name* and adds it to its symbol table with the specified parameters *value*, *type*, and *group*. The *group* parameter specifies the group number assigned to a module when it is loaded on the target; see the manual entry for **moduleLib**.
- RETURNS** OK, or ERROR if there is insufficient memory for the symbol to be allocated.
- SEE ALSO** **VXWSymTab**, **moduleLib**

VXWSymTab::each()

NAME **VXWSymTab::each()** – call a routine to examine each entry in a symbol table (WFC Opt.)

SYNOPSIS

```

SYMBOL * each
(
    FUNCPTR routine,
    int routineArg
)

```

DESCRIPTION This routine calls a user-supplied routine to examine each entry in the symbol table; it calls the specified routine once for each entry. The routine must have the following type signature:

```

BOOL routine
(
    char * name, /* entry name */
    int val, /* value associated with entry */
    SYM_TYPE type, /* entry type */
    int arg, /* arbitrary user-supplied arg */
    UINT16 group /* group number */
)

```

The user-supplied routine must return TRUE if **VXWSymTab::each()** is to continue calling it for each entry, or FALSE if it is done and **VXWSymTab::each()** can exit.

RETURNS A pointer to the last symbol reached, or NULL if all symbols are reached.

SEE ALSO **VXWSymTab**

VXWSymTab::findByName()

NAME VXWSymTab::findByName() – look up a symbol by name (WFC Opt.)

SYNOPSIS

```
STATUS findByName
(
    char *    name,
    char *    *pValue,
    SYM_TYPE * pType
) const
```

DESCRIPTION This routine searches its symbol table for a symbol matching a specified name. If the symbol is found, its value and type are copied to *pValue* and *pType*. If multiple symbols have the same name but differ in type, the routine chooses the matching symbol most recently added to the symbol table.

RETURNS OK, or ERROR if the symbol cannot be found.

SEE ALSO VXWSymTab

VXWSymTab::findByNameAndType()

NAME VXWSymTab::findByNameAndType() – look up a symbol by name and type (WFC Opt.)

SYNOPSIS

```
STATUS findByNameAndType
(
    char *    name,
    char *    *pValue,
    SYM_TYPE * pType,
    SYM_TYPE  goalType,
    SYM_TYPE  mask
) const
```

DESCRIPTION This routine searches its symbol table for a symbol matching both name and type (*name* and *goalType*). If the symbol is found, its value and type are copied to *pValue* and *pType*. The *mask* parameter can be used to match sub-classes of type.

RETURNS OK, or ERROR if the symbol is not found.

SEE ALSO VXWSymTab

VXWSymTab::findByValue()

NAME VXWSymTab::findByValue() – look up a symbol by value (WFC Opt.)

SYNOPSIS

```
STATUS findByValue
(
    UINT      value,
    char *    name,
    int *     pValue,
    SYM_TYPE * pType
) const
```

DESCRIPTION This routine searches its symbol table for a symbol matching a specified value. If there is no matching entry, it chooses the table entry with the next lower value. The symbol name (with terminating EOS), the actual value, and the type are copied to *name*, *pValue*, and *pType*.

RETURNS OK, or ERROR if *value* is less than the lowest value in the table.

SEE ALSO VXWSymTab

VXWSymTab::findByValueAndType()

NAME VXWSymTab::findByValueAndType() – look up a symbol by value and type (WFC Opt.)

SYNOPSIS

```
STATUS findByValueAndType
(
    UINT      value,
    char *    name,
    int *     pValue,
    SYM_TYPE * pType,
    SYM_TYPE  goalType,
    SYM_TYPE  mask
) const
```

DESCRIPTION This routine searches a symbol table for a symbol matching both value and type (*value* and *goalType*). If there is no matching entry, it chooses the table entry with the next lower value. The symbol name (with terminating EOS), the actual value, and the type are copied to *name*, *pValue*, and *pType*. The *mask* parameter can be used to match sub-classes of type.

RETURNS OK, or ERROR if *value* is less than the lowest value in the table.

SEE ALSO VXWSymTab

VXWSymTab::remove()

NAME *VXWSymTab::remove()* – remove a symbol from a symbol table (WFC Opt.)

SYNOPSIS

```
STATUS remove
(
    char *   name,
    SYM_TYPE type
)
```

DESCRIPTION This routine removes a symbol of matching name and type from its symbol table. The symbol is deallocated if found. Note that VxWorks symbols in a standalone VxWorks image (where the symbol table is linked in) cannot be removed.

RETURNS OK, or ERROR if the symbol is not found or could not be deallocated.

SEE ALSO VXWSymTab

VXWSymTab::VXWSymTab()

NAME *VXWSymTab::VXWSymTab()* – create a symbol table (WFC Opt.)

SYNOPSIS

```
VXWSymTab
(
    int     hashSizeLog2,
    BOOL    sameNameOk,
    PART_ID symPartId
)
```

DESCRIPTION This constructor creates and initializes a symbol table with a hash table of a specified size. The size of the hash table is specified as a power of two. For example, if *hashSizeLog2* is 6, a 64-entry hash table is created.

If *sameNameOk* is FALSE, attempting to add a symbol with the same name and type as an already-existing symbol results in an error.

VXWSymTab::VXWSymTab()

Memory for storing symbols as they are added to the symbol table will be allocated from the memory partition *symPartId*. The ID of the system memory partition is stored in the global variable **memSysPartId**, which is declared in **memLib.h**.

RETURNS N/A

SEE ALSO **VXWSymTab**

VXWSymTab::VXWSymTab()

NAME **VXWSymTab::VXWSymTab()** – create a symbol-table object (WFC Opt.)

SYNOPSIS

```
VXWSymTab
(
    SYMTAB_ID aSymTabId
)
```

DESCRIPTION This constructor creates a symbol table object based on an existing symbol table. For example, the following statement creates a symbol-table object for the VxWorks system symbol table (assuming you have configured a target-resident symbol table into your VxWorks system):

```
VXWSymTab sSym;
...
sSym = VXWSymTab (sysSymTbl);
```

SEE ALSO **VXWSymTab**

VXWSymTab::~VXWSymTab()

NAME **VXWSymTab::~VXWSymTab()** – delete a symbol table (WFC Opt.)

SYNOPSIS

```
~VXWSymTab ( )
```

DESCRIPTION This routine deletes a symbol table; it deallocates all memory associated with its symbol table, including the hash table, and marks the table as invalid.

Deletion of a table that still contains symbols throws an error. Successful deletion includes the deletion of the internal hash table and the deallocation of memory associated with the table. The table is marked invalid to prohibit any future references.

RETURNS OK, or ERROR if the table still contains symbols.

SEE ALSO VXWSymTab

VXWTask::activate()

NAME *VXWTask::activate()* – activate a task (WFC Opt.)

SYNOPSIS `STATUS activate ()`

DESCRIPTION This routine activates tasks created by the form of the constructor that does not automatically activate a task. Without activation, a task is ineligible for CPU allocation by the scheduler.

RETURNS OK, or ERROR if the task cannot be activated.

SEE ALSO *VXWTask::VXWTask()*

VXWTask::deleteForce()

NAME *VXWTask::deleteForce()* – delete a task without restriction (WFC Opt.)

SYNOPSIS `STATUS deleteForce ()`

DESCRIPTION This routine deletes a task even if the task is protected from deletion. It is similar to *VXWTask::~~VXWTask()*. Upon deletion, all routines specified by *taskDeleteHookAdd()* are called in the context of the deleting task.

CAVEATS This routine is intended as a debugging aid, and is generally inappropriate for applications. Disregarding a task's deletion protection could leave the the system in an unstable state or lead to system deadlock.

The system does not protect against simultaneous *VXWTask::deleteForce()* calls. Such a situation could leave the system in an unstable state.

RETURNS OK, or ERROR if the task cannot be deleted.

SEE ALSO *taskDeleteHookAdd()*, *VXWTask::~~VXWTask()*

VXWTask::envCreate()

NAME *VXWTask::envCreate()* – create a private environment (WFC Opt.)

SYNOPSIS

```
STATUS envCreate
(
    int envSource
)
```

DESCRIPTION This routine creates a private set of environment variables for a specified task, if the environment variable task create hook is not installed.

RETURNS OK, or ERROR if memory is insufficient.

SEE ALSO *VXWTask*, *envLib*

VXWTask::errNo()

NAME *VXWTask::errNo()* – retrieve error status value (WFC Opt.)

SYNOPSIS

```
int errNo ()
```

DESCRIPTION This routine gets the error status for the task.

RETURNS The error status value contained in **errno**.

SEE ALSO *VXWTask*

VXWTask::errNo()

NAME *VXWTask::errNo()* – set error status value (WFC Opt.)

SYNOPSIS

```
STATUS errNo
(
    int errorValue
)
```

DESCRIPTION This routine sets the error status value for its task.

RETURNS OK.

SEE ALSO VXWTask

VXWTask::id()

NAME *VXWTask::id()* – reveal task ID (WFC Opt.)

SYNOPSIS `int id ()`

DESCRIPTION This routine reveals the task ID for its task. The task ID is necessary to call C routines that affect or inquire on a task.

RETURNS task ID

SEE ALSO VXWTask, taskLib

VXWTask::info()

NAME *VXWTask::info()* – get information about a task (WFC Opt.)

SYNOPSIS `STATUS info
(
TASK_DESC * pTaskDesc
) const`

DESCRIPTION This routine fills in a specified task descriptor (**TASK_DESC**) for its task. The information in the task descriptor is, for the most part, a copy of information kept in the task control block (**WIND_TCB**). The **TASK_DESC** structure is useful for common information and avoids dealing directly with the unwieldy **WIND_TCB**.

NOTE Examination of **WIND_TCBs** should be restricted to debugging aids.

RETURNS OK

SEE ALSO VXWTask

VXWTask::isReady()

VXWTask::isReady()

NAME *VXWTask::isReady()* – check if task is ready to run (WFC Opt.)

SYNOPSIS `BOOL isReady ()`

DESCRIPTION This routine tests the status field of its task to determine whether the task is ready to run.

RETURNS TRUE if the task is ready, otherwise FALSE.

SEE ALSO *VXWTask*

VXWTask::isSuspended()

NAME *VXWTask::isSuspended()* – check if task is suspended (WFC Opt.)

SYNOPSIS `BOOL isSuspended ()`

DESCRIPTION This routine tests the status field of its task to determine whether the task is suspended.

RETURNS TRUE if the task is suspended, otherwise FALSE.

SEE ALSO *VXWTask*

VXWTask::kill()

NAME *VXWTask::kill()* – send a signal to task (WFC Opt.)

SYNOPSIS `int kill
(
 int signo
)`

DESCRIPTION This routine sends a signal *signo* to its task.

RETURNS OK (0), or ERROR (-1) if the signal number is invalid.

ERRNO EINVAL
SEE ALSO VXWTask

VXWTask::name()

NAME ***VXWTask::name()*** – get the name associated with a task ID (WFC Opt.)

SYNOPSIS **char * name ()**

DESCRIPTION This routine returns a pointer to the name of its task, if it has a name; otherwise it returns NULL.

RETURNS A pointer to the task name, or NULL.

SEE ALSO VXWTask

VXWTask::options()

NAME ***VXWTask::options()*** – examine task options (WFC Opt.)

SYNOPSIS **STATUS options**
 (
 int * pOptions
) **const**

DESCRIPTION This routine gets the current execution options of its task. The option bits returned indicate the following modes:

VX_FP_TASK
 execute with floating-point coprocessor support.

VX_PRIVATE_ENV
 include private environment support (see **envLib**).

VX_NO_STACK_FILL
 do not fill the stack for use by **checkstack()**.

VX_UNBREAKABLE
 do not allow breakpoint debugging.

For definitions, see **taskLib.h**.

VXWTask::options()

RETURNS OK.

SEE ALSO VXWTask

VXWTask::options()

NAME *VXWTask::options()* – change task options (WFC Opt.)

SYNOPSIS

```
STATUS options
(
    int mask,
    int newOptions
)
```

DESCRIPTION This routine changes the execution options of its task. The only option that can be changed after a task has been created is:

VX_UNBREAKABLE – do not allow breakpoint debugging.

For definitions, see **taskLib.h**.

RETURNS OK.

SEE ALSO VXWTask

VXWTask::priority()

NAME *VXWTask::priority()* – examine the priority of task (WFC Opt.)

SYNOPSIS

```
STATUS priority
(
    int * pPriority
) const
```

DESCRIPTION This routine reports the current priority of its task. The current priority is copied to the integer pointed to by *pPriority*.

RETURNS OK.

SEE ALSO VXWTask

VXWTask::priority()

NAME *VXWTask::priority()* – change the priority of a task (WFC Opt.)

SYNOPSIS

```
STATUS priority
(
    int newPriority
)
```

DESCRIPTION This routine changes its task's priority to a specified priority. Priorities range from 0, the highest priority, to 255, the lowest priority.

RETURNS OK.

SEE ALSO *VXWTask*

VXWTask::registers()

NAME *VXWTask::registers()* – set a task's registers (WFC Opt.)

SYNOPSIS

```
STATUS registers
(
    const REG_SET * pRegs
)
```

DESCRIPTION This routine loads a specified register set *pRegs* into the task's TCB.

NOTE This routine only works well if the task is known not to be in the ready state. Suspending the task before changing the register set is recommended.

RETURNS OK.

SEE ALSO *VXWTask::suspend()*

VXWTask::registers()

VXWTask::registers()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | VXWTask::registers() – get task registers from the TCB (WFC Opt.) |
| SYNOPSIS | <pre> STATUS registers (REG_SET * pRegs) const </pre> |
| DESCRIPTION | This routine gathers task information kept in the TCB. It copies the contents of the task's registers to the register structure <i>pRegs</i> . |
| NOTE | This routine only works well if the task is known to be in a stable, non-executing state. Self-examination, for instance, is not advisable, as results are unpredictable. |
| RETURNS | OK. |
| SEE ALSO | VXWTask::suspend() |

VXWTask::restart()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | VXWTask::restart() – restart task (WFC Opt.) |
| SYNOPSIS | <pre> STATUS restart () </pre> |
| DESCRIPTION | This routine "restarts" its task. The task is first terminated, and then reinitialized with the same ID, priority, options, original entry point, stack size, and parameters it had when it was terminated. Self-restarting of a calling task is performed by the exception task. |
| NOTE | If the task has modified any of its start-up parameters, the restarted task will start with the changed values. |
| RETURNS | OK, or ERROR if the task could not be restarted. |
| SEE ALSO | VXWTask |

VXWTask::resume()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------|
| NAME | VXWTask::resume() – resume task (WFC Opt.) |
| SYNOPSIS | <code>STATUS resume ()</code> |
| DESCRIPTION | This routine resumes its task. Suspension is cleared, and the task operates in the remaining state. |
| RETURNS | OK, or ERROR if the task cannot be resumed. |
| SEE ALSO | VXWTask |

VXWTask::show()

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|--------|------|--------|------|----------|------|---|------|--------|------|--------|------|---|------|----------|------|---|------|---|------|-------|------|-------|------|--------|------|---|------|--------|------|--------|------|------|------|-------|--|--|--|--|
| NAME | VXWTask::show() – display the contents of task registers (WFC Opt.) | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| SYNOPSIS | <code>void show ()</code> | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| DESCRIPTION | This routine displays the register contents of its task on standard output. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| EXAMPLE | The following shell command line displays the register of a task vxwT28 : <code>-> vxwT28.show ()</code> The example prints on standard output a display like the following (68000 family): <table><tr><td>d0 =</td><td>0</td><td>d1 =</td><td>0</td><td>d2 =</td><td>578fe</td><td>d3 =</td><td>1</td></tr><tr><td>d4 =</td><td>3e84e1</td><td>d5 =</td><td>3e8568</td><td>d6 =</td><td>0</td><td>d7 =</td><td>ffffffff</td></tr><tr><td>a0 =</td><td>0</td><td>a1 =</td><td>0</td><td>a2 =</td><td>4f06c</td><td>a3 =</td><td>578d0</td></tr><tr><td>a4 =</td><td>3fffc4</td><td>a5 =</td><td>0</td><td>fp =</td><td>3e844c</td><td>sp =</td><td>3e842c</td></tr><tr><td>sr =</td><td>3000</td><td>pc =</td><td>4f0f2</td><td></td><td></td><td></td><td></td></tr></table> | d0 = | 0 | d1 = | 0 | d2 = | 578fe | d3 = | 1 | d4 = | 3e84e1 | d5 = | 3e8568 | d6 = | 0 | d7 = | ffffffff | a0 = | 0 | a1 = | 0 | a2 = | 4f06c | a3 = | 578d0 | a4 = | 3fffc4 | a5 = | 0 | fp = | 3e844c | sp = | 3e842c | sr = | 3000 | pc = | 4f0f2 | | | | |
| d0 = | 0 | d1 = | 0 | d2 = | 578fe | d3 = | 1 | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| d4 = | 3e84e1 | d5 = | 3e8568 | d6 = | 0 | d7 = | ffffffff | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| a0 = | 0 | a1 = | 0 | a2 = | 4f06c | a3 = | 578d0 | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| a4 = | 3fffc4 | a5 = | 0 | fp = | 3e844c | sp = | 3e842c | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| sr = | 3000 | pc = | 4f0f2 | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| RETURNS | N/A | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| SEE ALSO | VXWTask | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

VXWTask::show()

VXWTask::show()**NAME** VXWTask::show() – display task information from TCBs (WFC Opt.)**SYNOPSIS**

```
STATUS show
(
    int level
) const
```

DESCRIPTION This routine displays the contents of its task's task control block (TCB). If *level* is 1, it also displays task options and registers. If *level* is 2, it displays all tasks.

The TCB display contains the following fields:

| Field | Meaning |
|--------|----------------------------------------------------------------------------|
| NAME | Task name |
| ENTRY | Symbol name or address where task began execution |
| TID | Task ID |
| PRI | Priority |
| STATUS | Task status, as formatted by <i>taskStatusString()</i> |
| PC | Program counter |
| SP | Stack pointer |
| ERRNO | Most recent error code for this task |
| DELAY | If task is delayed, number of clock ticks remaining in delay (0 otherwise) |

EXAMPLE The following example shows the TCB contents for a task named **t28**:

```

NAME          ENTRY      TID    PRI  STATUS      PC          SP          ERRNO  DELAY
-----
t28           _appStart 20efcac  1  READY      201dc90  20ef980      0      0
stack: base 0x20efcac end 0x20ed59c size 9532 high 1452 margin 8080
options: 0x1e
VX_UNBREAKABLE      VX_DEALLOC_STACK      VX_FP_TASK      VX_STDIO
D0 = 0  D4 = 0  A0 = 0  A4 = 0
D1 = 0  D5 = 0  A1 = 0  A5 = 203a084  SR = 3000
D2 = 0  D6 = 0  A2 = 0  A6 = 20ef9a0  PC = 2038614
D3 = 0  D7 = 0  A3 = 0  A7 = 20ef980
```

RETURNS N/A**SEE ALSO** *VXWTaskstatusString()*, *Tornado User's Guide: The Tornado Shell*

VXWTask::sigqueue()

NAME VXWTask::sigqueue() – send a queued signal to task (WFC Opt.)

SYNOPSIS

```
int sigqueue
(
    int          signo,
    const union signal value
)
```

DESCRIPTION The routine *sigqueue()* sends to its task the signal specified by *signo* with the signal-parameter value specified by *value*.

RETURNS OK (0), or ERROR (-1) if the signal number is invalid, or if there are no queued-signal buffers available.

ERRNO EINVAL EAGAIN

SEE ALSO VXWTask

VXWTask::SRSet()

NAME VXWTask::SRSet() – set the task status register (MC680x0, MIPS, i386/i486) (WFC Opt.)

SYNOPSIS

```
STATUS SRSet
(
    UINT16 sr
)
```

SYNOPSIS (i80X86)

```
STATUS SRSet
(
    UINT sr
)
```

SYNOPSIS (MIPS)

```
STATUS SRSet
(
    UINT32 sr
)
```

VXWTask::statusString()

This routine sets the status register of a task that is not running; that is, you must not call this >*SRSet()*. Debugging facilities use this routine to set the trace bit in the status register of a task that is being single-stepped.

RETURNS OK.

SEE ALSO VXWTask

VXWTask::statusString()

NAME VXWTask::statusString() – get task status as a string (WFC Opt.)

SYNOPSIS

```
STATUS statusString
(
    char * pString
) const
```

DESCRIPTION This routine deciphers the WIND task status word in the TCB for its task, and copies the appropriate string to *pString*.

The formatted string is one of the following:

| String | Meaning |
|----------|----------------------------------------------------------------------------|
| READY | Task is not waiting for any resource other than the CPU. |
| PEND | Task is blocked due to the unavailability of some resource. |
| DELAY | Task is asleep for some duration. |
| SUSPEND | Task is unavailable for execution (but not suspended, delayed, or pended). |
| DELAY+S | Task is both delayed and suspended. |
| PEND+S | Task is both pended and suspended. |
| PEND+T | Task is pended with a timeout. |
| PEND+S+T | Task is pended with a timeout, and also suspended. |
| ...+I | Task has inherited priority (+I may be appended to any string above). |
| DEAD | Task no longer exists. |

RETURNS OK.

SEE ALSO VXWTask

VXWTask::suspend()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>VXWTask::suspend()</i> – suspend task (WFC Opt.) |
| SYNOPSIS | <code>STATUS suspend ()</code> |
| DESCRIPTION | <p>This routine suspends its task. Suspension is additive: thus, tasks can be delayed and suspended, or pended and suspended. Suspended, delayed tasks whose delays expire remain suspended. Likewise, suspended, pended tasks that unblock remain suspended only.</p> <p>Care should be taken with asynchronous use of this facility. The task is suspended regardless of its current state. The task could, for instance, have mutual exclusion to some system resource, such as the network or system memory partition. If suspended during such a time, the facilities engaged are unavailable, and the situation often ends in deadlock.</p> <p>This routine is the basis of the debugging and exception handling packages. However, as a synchronization mechanism, this facility should be rejected in favor of the more general semaphore facility.</p> |
| RETURNS | OK, or ERROR if the task cannot be suspended. |
| SEE ALSO | <i>VXWTask</i> |

VXWTask::tcb()

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | <i>VXWTask::tcb()</i> – get the task control block (WFC Opt.) |
| SYNOPSIS | <code>WIND_TCB * tcb ()</code> |
| DESCRIPTION | <p>This routine returns a pointer to the task control block (<code>WIND_TCB</code>) for its task. Although all task state information is contained in the TCB, users must not modify it directly. To change registers, for instance, use <i>VXWTask::registers()</i>.</p> |
| RETURNS | A pointer to a <code>WIND_TCB</code> . |
| SEE ALSO | <i>VXWTask</i> |

VXWTask::varAdd()

NAME VXWTask::varAdd() – add a task variable to task (WFC Opt.)

SYNOPSIS

```
STATUS varAdd
(
    int * pVar
)
```

DESCRIPTION This routine adds a specified variable *pVar* (4-byte memory location) to its task's context. After calling this routine, the variable is private to the task. The task can access and modify the variable, but the modifications are not visible to other tasks, and other tasks' modifications to that variable do not affect the value seen by the task. This is accomplished by saving and restoring the variable's initial value each time a task switch occurs to or from the calling task.

This facility can be used when a routine is to be spawned repeatedly as several independent tasks. Although each task has its own stack, and thus separate stack variables, they all share the same static and global variables. To make a variable *not* shareable, the routine can call **VXWTask::varAdd()** to make a separate copy of the variable for each task, but all at the same physical address.

Note that task variables increase the task switch time to and from the tasks that own them. Therefore, it is desirable to limit the number of task variables that a task uses. One efficient way to use task variables is to have a single task variable that is a pointer to a dynamically allocated structure containing the task's private data.

EXAMPLE Assume that three identical tasks are spawned with a main routine called *operator()*. All three use the structure **OP_GLOBAL** for all variables that are specific to a particular incarnation of the task. The following code fragment shows how this is set up:

```
OP_GLOBAL *opGlobal; // ptr to operator task's global variables
VXWTask me; // task object for self
void operator
(
    int opNum // number of this operator task
)
{
    me = VXWTask (0); // task object for running task
    if (me.varAdd ((int *)&opGlobal) != OK)
    {
        printErr ("operator%d: can't VXWTask::varAdd opGlobal\n", opNum);
        me.suspend ();
    }
    if ((opGlobal = (OP_GLOBAL *) malloc (sizeof (OP_GLOBAL))) == NULL)
```

```

        {
        printErr ("operator%d: can't malloc opGlobal\n", opNum);
        me.suspend ();
        }
    ...
}

```

RETURNS OK, or ERROR if memory is insufficient for the task variable descriptor.

SEE ALSO *VXWTask::varDelete()*, *VXWTask::varGet()*, *VXWTask::varSet()*

VXWTask::varDelete()

NAME *VXWTask::varDelete()* – remove a task variable from task (WFC Opt.)

SYNOPSIS

```

STATUS varDelete
(
    int * pVar
)

```

DESCRIPTION This routine removes a specified task variable, *pVar*, from its task’s context. The private value of that variable is lost.

RETURNS OK, or ERROR if the task variable does not exist for the task.

SEE ALSO *VXWTask::varAdd()*, *VXWTask::varGet()*, *VXWTask::varSet()*

VXWTask::varGet()

NAME *VXWTask::varGet()* – get the value of a task variable (WFC Opt.)

SYNOPSIS

```

int varGet
(
    int * pVar
) const

```

DESCRIPTION This routine returns the private value of a task variable for its task. The task is usually not the calling task, which can get its private value by directly accessing the variable. This routine is provided primarily for debugging purposes.

VXWTask::varInfo()

- RETURNS** The private value of the task variable, or ERROR if the task does not own the task variable.
- SEE ALSO** *VXWTask::varAdd()*, *VXWTask::varDelete()*, *VXWTask::varSet()*

VXWTask::varInfo()

- NAME** *VXWTask::varInfo()* – get a list of task variables (WFC Opt.)
- SYNOPSIS**
- ```
int varInfo
(
 TASK_VAR varList[],
 int maxVars
) const
```
- DESCRIPTION** This routine provides the calling task with a list of all of the task variables of its task. The unsorted array of task variables is copied to *varList*.
- CAVEATS** Kernel rescheduling is disabled while task variables are looked up.
- There is no guarantee that all the task variables are still valid or that new task variables have not been created by the time this routine returns.
- RETURNS** The number of task variables in the list.
- SEE ALSO** *VXWTask*

---

## ***VXWTask::varSet()***

- NAME** *VXWTask::varSet()* – set the value of a task variable (WFC Opt.)
- SYNOPSIS**
- ```
STATUS varSet
(
    int * pVar,
    int  value
)
```

DESCRIPTION This routine sets the private value of the task variable for a specified task. The specified task is usually not the calling task, which can set its private value by directly modifying the variable. This routine is provided primarily for debugging purposes.

RETURNS OK, or ERROR if the task does not own the task variable.

SEE ALSO *VXWTask::varAdd()*, *VXWTask::varDelete()*, *VXWTask::varGet()*

VXWTask::VXWTask()

NAME *VXWTask::VXWTask()* – initialize a task object (WFC Opt.)

SYNOPSIS

```
VXWTask
(
    int tid
)
```

DESCRIPTION This constructor creates a task object from the task ID of an existing task. Because of the VxWorks convention that a task ID of 0 refers to the calling task, this constructor can be used to derive a task object for the calling task, as follows:

```
myTask = VXWTask (0);
```

RETURNS N/A

SEE ALSO *taskLib*, *VXWTask::~~VXWTask()*, *sp()*

VXWTask::VXWTask()

NAME *VXWTask::VXWTask()* – create and spawn a task (WFC Opt.)

SYNOPSIS

```
VXWTask
(
    char * name,
    int priority,
    int options,
    int stackSize,
    FUNCPTR entryPoint,
    int arg1=0,
```

VXWTask::VXWTask()

```

    int    arg2=0,
    int    arg3=0,
    int    arg4=0,
    int    arg5=0,
    int    arg6=0,
    int    arg7=0,
    int    arg8=0,
    int    arg9=0,
    int    arg10=0
)

```

DESCRIPTION

This constructor creates and activates a new task with a specified priority and options.

A task may be assigned a name as a debugging aid. This name appears in displays generated by various system information facilities such as *i()*. The name may be of arbitrary length and content, but the current VxWorks convention is to limit task names to ten characters and prefix them with a "t". If *name* is specified as NULL, an ASCII name is assigned to the task of the form "tn" where *n* is an integer which increments as new tasks are spawned.

The only resource allocated to a spawned task is a stack of a specified size *stackSize*, which is allocated from the system memory partition. Stack size should be an even integer. A task control block (TCB) is carved from the stack, as well as any memory required by the task name. The remaining memory is the task's stack and every byte is filled with the value 0xEE for the *checkStack()* facility. See the manual entry for *checkStack()* for stack-size checking aids.

The entry address *entryPt* is the address of the "main" routine of the task. The routine is called after the C environment is set up. The specified routine is called with the ten arguments provided. Should the specified main routine return, a call to *exit()* is made automatically.

Note that ten (and only ten) arguments must be passed for the spawned function.

Bits in the options argument may be set to run with the following modes:

VX_FP_TASK

execute with floating-point coprocessor support.

VX_PRIVATE_ENV

include private environment support.

VX_NO_STACK_FILL

do not fill the stack for use by *checkstack()*.

VX_UNBREAKABLE

do not allow breakpoint debugging.

See the definitions in **taskLib.h**.

RETURNS

N/A

SEE ALSO *VXWTask::~VXWTask()*, *VXWTask::activate()*, *sp()*, *VxWorks Programmer's Guide: Basic OS*

VXWTask::VXWTask()

NAME *VXWTask::VXWTask()* – initialize a task with a specified stack (WFC Opt.)

SYNOPSIS

```
VXWTask
(
    WIND_TCB * pTcb,
    char *     name,
    int        priority,
    int        options,
    char *     pStackBase,
    int        stackSize,
    FUNCPTR    entryPoint,
    int        arg1=0,
    int        arg2=0,
    int        arg3=0,
    int        arg4=0,
    int        arg5=0,
    int        arg6=0,
    int        arg7=0,
    int        arg8=0,
    int        arg9=0,
    int        arg10=0
)
```

DESCRIPTION This constructor initializes user-specified regions of memory for a task stack and control block instead of allocating them from memory. This constructor uses the specified pointers to the `WIND_TCB` and stack as the components of the task. This allows, for example, the initialization of a static `WIND_TCB` variable. It also allows for special stack positioning as a debugging aid.

As in other constructors, a task may be given a name. If no name is specified, this constructor creates a task without a name (rather than assigning a default name).

Other arguments are the same as in the previous constructor. This constructor does not activate the task. This must be done by calling *VXWTask::activate()*.

Normally, tasks should be started using the previous constructor rather than this one, except when additional control is required for task memory allocation or a separate task activation is desired.

VXWTask::~~VXWTask()

RETURNS OK, or ERROR if the task cannot be initialized.

SEE ALSO *VXWTask::activate()*

VXWTask::~~VXWTask()

NAME *VXWTask::~~VXWTask()* – delete a task (WFC Opt.)

SYNOPSIS `virtual ~VXWTask ()`

DESCRIPTION This destructor causes the task to cease to exist and deallocates the stack and **WIND_TCB** memory resources. Upon deletion, all routines specified by *taskDeleteHookAdd()* are called in the context of the deleting task.

RETURNS N/A

SEE ALSO *excLib*, *taskDeleteHookAdd()*, *VXWTask::VXWTask()*, *VxWorks Programmer's Guide: Basic OS*

VXWWd::cancel()

NAME *VXWWd::cancel()* – cancel a currently counting watchdog (WFC Opt.)

SYNOPSIS `STATUS cancel ()`

DESCRIPTION This routine cancels a currently running watchdog timer by zeroing its delay count. Watchdog timers may be canceled from interrupt level.

RETURNS OK, or ERROR if the watchdog timer cannot be canceled.

SEE ALSO *VXWWd::start()*

VXWwd::start()

| | |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | VXWwd::start() – start a watchdog timer (WFC Opt.) |
| SYNOPSIS | <pre>STATUS start (int delay, FUNCPTR pRoutine, int parameter)</pre> |
| DESCRIPTION | <p>This routine adds a watchdog timer to the system tick queue. The specified watchdog routine will be called from interrupt level after the specified number of ticks has elapsed. Watchdog timers may be started from interrupt level.</p> <p>To replace either the timeout <i>delay</i> or the routine to be executed, call VXWwd::start() again; only the most recent VXWwd::start() on a given watchdog ID has any effect. (If your application requires multiple watchdog routines, use VXWwd::VXWwd() to generate separate a watchdog for each.) To cancel a watchdog timer before the specified tick count is reached, call VXWwd::cancel().</p> <p>Watchdog timers execute only once, but some applications require periodically executing timers. To achieve this effect, the timer routine itself must call VXWwd::start() to restart the timer on each invocation.</p> |
| WARNING | The watchdog routine runs in the context of the system-clock ISR; thus, it is subject to all ISR restrictions. |
| RETURNS | OK, or ERROR if the watchdog timer cannot be started. |
| SEE ALSO | VXWwd::cancel() |

VXWwd::VXWwd()

| | |
|--------------------|--------------------------------------------------------|
| NAME | VXWwd::VXWwd() – construct a watchdog timer (WFC Opt.) |
| SYNOPSIS | <pre>vxwwd ()</pre> |
| DESCRIPTION | This routine creates a watchdog timer. |
| RETURNS | N/A |
| SEE ALSO | VXWwd::~VXWwd() |

VXWwd::VXWwd()

VXWwd::VXWwd()

NAME VXWwd::VXWwd() – construct a watchdog timer (WFC Opt.)

SYNOPSIS

```
VXWwd  
(  
    WDOG_ID aWdId  
)
```

DESCRIPTION This routine creates a watchdog timer from an existing WDOG_ID.

RETURNS N/A

SEE ALSO VXWwd::~~VXWwd()

VXWwd::~~VXWwd()

NAME VXWwd::~~VXWwd() – destroy a watchdog timer (WFC Opt.)

SYNOPSIS

```
~VXWwd ( )
```

DESCRIPTION This routine destroys a watchdog timer. The watchdog will be removed from the timer queue if it has been started.

RETURNS N/A

SEE ALSO VXWwd::VXWwd()

wcstombs()

| | |
|----------------------|-------------------------------------------------------------------------------------------------------|
| NAME | <i>wcstombs()</i> – convert a series of wide char’s to multibyte char’s (Unimplemented) (ANSI) |
| SYNOPSIS | <pre>size_t wcstombs (char * s, const wchar_t * pwcs, size_t n)</pre> |
| DESCRIPTION | This multibyte character function is unimplemented in VxWorks. |
| INCLUDE FILES | <code>stdlib.h</code> |

wd33c93CtrlCreate()

NAME *wd33c93CtrlCreate()* – create and partially initialize a WD33C93 SBIC structure

SYNOPSIS

```
WD_33C93_SCSI_CTRL *wd33c93CtrlCreate
(
    UINT8 * sbicBaseAdrs, /* base address of SBIC */
    int    regOffset,     /* addr offset between consecutive regs. */
    UINT   clkPeriod,     /* period of controller clock (nsec) */
    int    devType,       /* SBIC device type */
    FUNCPTR sbicScsiReset, /* SCSI bus reset function */
    FUNCPTR sbicDmaBytesIn, /* SCSI DMA input function */
    FUNCPTR sbicDmaBytesOut /* SCSI DMA output function */
)
```

DESCRIPTION This routine creates an SBIC data structure and must be called before using an SBIC chip. It should be called once and only once for a specified SBIC. Since it allocates memory for a structure needed by all routines in **wd33c93Lib**, it must be called before any other routines in the library. After calling this routine, at least one call to *wd33c93CtrlInit()* should be made before any SCSI transaction is initiated using the SBIC.

Note that only the non-multiplexed processor interface is supported.

The input parameters are as follows:

sbicBaseAdrs

the address where the CPU accesses the lowest register of the SBIC.

regOffset

the address offset (in bytes) to access consecutive registers. (This must be a power of 2; for example, 1, 2, 4, etc.)

clkPeriod

the period, in nanoseconds, of the signal-to-SBIC clock input used only for select command timeouts.

devType

a constant corresponding to the type (part number) of this controller; possible options are enumerated in **wd33c93.h** under the heading "SBIC device type."

sbicScsiReset

a board-specific routine to assert the RST line on the SCSI bus, which causes all connected devices to return to a known quiescent state.

spcDmaBytesIn and *spcDmaBytesOut*

board-specific routines to handle DMA input and output. If these are NULL (0), SBIC program transfer mode is used. DMA is implemented only during SCSI data in/out phases. The interface to these DMA routines must be of the form:

```

STATUS xxDmaBytes{In, Out}
(
    SCSI_PHYS_DEV *pScsiPhysDev, /* ptr to phys dev info */
    UINT8         *pBuffer,      /* ptr to the data buffer */
    int           bufLength      /* number of bytes to xfer */
)

```

RETURNS A pointer to the SBIC control structure, or NULL if memory is insufficient or parameters are invalid.

SEE ALSO wd33c93Lib1, wd33c93.h

wd33c93CtrlCreateScsi2()

NAME *wd33c93CtrlCreateScsi2()* – create and partially initialize an SBIC structure

SYNOPSIS

```

WD_33C93_SCSI_CTRL *wd33c93CtrlCreateScsi2
(
    UINT8 * sbicBaseAdrs,      /* base address of the SBIC */
    int    regOffset,         /* address offset between SBIC registers */
    UINT   clkPeriod,         /* period of the SBIC clock (nsec) */
    FUNCPTR sysScsiBusReset, /* function to reset SCSI bus */
    int     sysScsiResetArg,  /* argument to pass to above function */
    UINT    sysScsiDmaMaxBytes, /* maximum byte count using DMA */
    FUNCPTR sysScsiDmaStart, /* function to start SCSI DMA transfer */
    FUNCPTR sysScsiDmaAbort, /* function to abort SCSI DMA transfer */
    int     sysScsiDmaArg    /* argument to pass to above functions */
)

```

DESCRIPTION This routine creates an SBIC data structure and must be called before using an SBIC chip. It must be called exactly once for a specified SBIC. Since it allocates memory for a structure needed by all routines in **wd33c93Lib2**, it must be called before any other routines in the library. After calling this routine, at least one call to *wd33c93CtrlInit()* must be made before any SCSI transaction is initiated using the SBIC.

NOTE Only the non-multiplexed processor interface is supported.

A detailed description of the input parameters follows:

sbicBaseAdrs

the address at which the CPU would access the lowest (AUX STATUS) register of the SBIC.

regOffset

the address offset (bytes) to access consecutive registers. (This must be a power of 2, for example, 1, 2, 4, etc.)

clkPeriod

the period in nanoseconds of the signal to SBIC CLK input.

sysScsiBusReset and **sysScsiResetArg**

the board-specific routine to pulse the SCSI bus RST signal. The specified argument is passed to this routine when it is called. It may be used to identify the SCSI bus to be reset, if there is a choice. The interface to this routine is of the form:

```
void xxBusReset
(
    int arg;                /* call-back argument */
)
```

sysScsiDmaMaxBytes, **sysScsiDmaStart**, **sysScsiDmaAbort**, and **sysScsiDmaArg**

board-specific routines to handle DMA transfers to and from the SBIC; if the maximum DMA byte count is zero, programmed I/O is used. Otherwise, non-NULL function pointers to DMA start and abort routines must be provided. The specified argument is passed to these routines when they are called; it may be used to identify the DMA channel to use, for example. Note that DMA is implemented only during SCSI data in/out phases. The interface to these DMA routines must be of the form:

```
STATUS xxDmaStart
(
    int arg;                /* call-back argument */
    UINT8 *pBuffer;        /* ptr to the data buffer */
    UINT buflength;        /* number of bytes to xfer */
    int direction;         /* 0 = SCSI->mem, 1 = mem->SCSI */
)
STATUS xxDmaAbort
(
    int arg;                /* call-back argument */
)
```

RETURNS

A pointer to the SBIC structure, or NULL if memory is insufficient or the parameters are invalid.

SEE ALSO

wd33c93Lib2

wd33c93CtrlInit()

NAME *wd33c93CtrlInit()* – initialize the user-specified fields in an SBIC structure

SYNOPSIS

```
STATUS wd33c93CtrlInit
(
    int * pSbic,           /* ptr to SBIC info */
    int  scsiCtrlBusId,   /* SCSI bus ID of this SBIC */
    UINT defaultSelTimeout, /* default dev. select timeout (microsec) */
    int  scsiPriority     /* priority of task when doing SCSI I/O */
)
```

DESCRIPTION This routine initializes an SBIC structure, after the structure is created with either *wd33c93CtrlCreate()* or *wd33c93CtrlCreateScsi2()*. This structure must be initialized before the SBIC can be used. It may be called more than once; however, it should be called only while there is no activity on the SCSI interface.

Before returning, this routine pulses RST (reset) on the SCSI bus, thus resetting all attached devices.

The input parameters are as follows:

pSbic

a pointer to the `WD_33C93_SCSI_CTRL` structure created with *wd33c93CtrlCreate()* or *wd33c93CtrlCreateScsi2()*.

scsiCtrlBusId

the SCSI bus ID of the SBIC, in the range 0 – 7. The ID is somewhat arbitrary; the value 7, or highest priority, is conventional.

defaultSelTimeout

the timeout, in microseconds, for selecting a SCSI device attached to this controller. This value is used as a default if no timeout is specified in *scsiPhysDevCreate()*. The recommended value zero (0) specifies `SCSI_DEF_SELECT_TIMEOUT` (250 millisec). The maximum timeout possible is approximately 2 seconds. Values exceeding this revert to the maximum. For more information about chip timeouts, see the manuals *Western Digital WD33C92/93 SCSI-Bus Interface Controller*, *Western Digital WD33C92A/93A SCSI-Bus Interface Controller*.

scsiPriority

the priority to which a task is set when performing a SCSI transaction. Valid priorities are 0 to 255. Alternatively, the value -1 specifies that the priority should not be altered during SCSI transactions.

RETURNS OK, or ERROR if a parameter is out of range.

SEE ALSO *wd33c93Lib*, *scsiPhysDevCreate()*, *Western Digital WD33C92/93 SCSI-Bus Interface Controller*, *Western Digital WD33C92A/93A SCSI-Bus Interface Controller*

wd33c93Show()

NAME *wd33c93Show()* – display the values of all readable WD33C93 chip registers

SYNOPSIS

```
int wd33c93Show
(
    int * pScsiCtrl /* ptr to SCSI controller info */
)
```

DESCRIPTION This routine displays the state of the SBIC registers in a user-friendly manner. It is useful primarily for debugging. It should not be invoked while another running process is accessing the SCSI controller.

EXAMPLE

```
-> wd33c93Show
REG #00 (Own ID           ) = 0x07
REG #01 (Control         ) = 0x00
REG #02 (Timeout Period ) = 0x20
REG #03 (Sectors        ) = 0x00
REG #04 (Heads          ) = 0x00
REG #05 (Cylinders MSB  ) = 0x00
REG #06 (Cylinders LSB  ) = 0x00
REG #07 (Log. Addr. MSB ) = 0x00
REG #08 (Log. Addr. 2SB ) = 0x00
REG #09 (Log. Addr. 3SB ) = 0x00
REG #0a (Log. Addr. LSB ) = 0x00
REG #0b (Sector Number  ) = 0x00
REG #0c (Head Number    ) = 0x00
REG #0d (Cyl. Number MSB) = 0x00
REG #0e (Cyl. Number LSB) = 0x00
REG #0f (Target LUN     ) = 0x00
REG #10 (Command Phase  ) = 0x00
REG #11 (Synch. Transfer) = 0x00
REG #12 (Xfer Count MSB ) = 0x00
REG #13 (Xfer Count 2SB ) = 0x00
REG #14 (Xfer Count LSB ) = 0x00
REG #15 (Destination ID ) = 0x03
REG #16 (Source ID      ) = 0x00
REG #17 (SCSI Status    ) = 0x42
REG #18 (Command       ) = 0x07
```

RETURNS OK, or ERROR if *pScsiCtrl* and *pSysScsiCtrl* are both NULL.

SEE ALSO wd33c93Lib

wdbNetromPktDevInit()

NAME *wdbNetromPktDevInit()* – initialize a NETROM packet device for the WDB agent

SYNOPSIS

```
void wdbNetromPktDevInit
(
    WDB_NETROM_PKT_DEV * pPktDev,    /* packet device to initialize */
    caddr_t             dpBase,      /* address of dualport memory */
    int                 width,       /* number of bytes in a ROM word */
    int                 index,       /* pod zero's index in a ROM word */
    int                 numAccess,   /* to pod zero per byte read */
    void (*             stackRcv)(), /* callback when packet arrives */
    int                 pollDelay    /* poll task delay */
)
```

DESCRIPTION This routine initializes a NETROM packet device. It is typically called from **usrWdb.c** when the WDB agents NETROM communication path is selected. The *dpBase* parameter is the address of NetROM's dualport RAM. The *width* parameter is the width of a word in ROM space, and can be 1, 2, or 4 to select 8-bit, 16-bit, or 32-bit width respectively (use the macro **WDB_NETROM_WIDTH** in **configAll.h** for this parameter). The *index* parameter refers to which byte of the ROM contains pod zero. The *numAccess* parameter should be set to the number of accesses to POD zero that are required to read a byte. It is typically one, but some boards actually read a word at a time. This routine spawns a task which polls the NetROM for incoming packets every *pollDelay* clock ticks.

RETURNS N/A

SEE ALSO wdbNetromPktDrv

wdbPipePktDevInit()

NAME *wdbPipePktDevInit()* – initialize a pipe packet device.

SYNOPSIS

```
STATUS wdbPipePktDevInit
(
    WDB_PIPE_PKT_DEV * pPktDev,    /* pipe device structure to init */
    void (*          stackRcv)() /* receive packet callback (udpRcv) */
)
```

SEE ALSO *wdbPipePktDrv*

wdbSlipPktDevInit()

NAME *wdbSlipPktDevInit()* – initialize a SLIP packet device for a WDB agent

SYNOPSIS

```
void wdbSlipPktDevInit
(
    WDB_SLIP_PKT_DEV * pPktDev,    /* SLIP packetizer device */
    SIO_CHAN *        pSioChan,    /* underlying serial channel */
    void (*          stackRcv)() /* callback when a packet arrives */
)
```

DESCRIPTION This routine initializes a SLIP packet device on one of the BSP's serial channels. It is typically called from **usrWdb.c** when the WDB agent's lightweight SLIP communication path is selected.

RETURNS N/A

SEE ALSO *wdbSlipPktDrv*

wdbSystemSuspend()

NAME *wdbSystemSuspend()* – suspend the system.

SYNOPSIS

```
STATUS wdbSystemSuspend (void)
```

DESCRIPTION This routine transfers control from the run time system to the WDB agent running in external mode. In order to give back the control to the system it must be resumed by the the external WDB agent.

EXAMPLE The code below, called in a vxWorks application, suspends the system :

```
if (wdbSystemSuspend != OK)
    printf ("External mode is not supported by the WDB agent.\n");
```

From a host tool, we can detect that the system is suspended.

First, attach to the target server :

```
wtxtcl> wtxToolAttach EP960CX
EP960CX_ps@sevre
```

Then, you can get the agent mode :

```
wtxtcl> wtxAgentModeGet
AGENT_MODE_EXTERN
```

To get the status of the system context, execute :

```
wtxtcl> wtxContextStatusGet CONTEXT_SYSTEM 0
CONTEXT_SUSPENDED
```

In order to resume the system, simply execute :

```
wtxtcl> wtxContextResume CONTEXT_SYSTEM 0
0
```

You will see that the system is now running :

```
wtxtcl> wtxContextStatusGet CONTEXT_SYSTEM 0
CONTEXT_RUNNING
```

RETURNS OK upon successful completion, ERROR if external mode is not supported by the WDB agent.

SEE ALSO **wdbLib**

wdbTsfsDrv()

- NAME** *wdbTsfsDrv()* – initialize the TSFS device driver for a WDB agent
- SYNOPSIS**
- ```
STATUS wdbTsfsDrv
(
 char * name /* root name in i/o system */
)
```
- DESCRIPTION**
- This routine initializes the VxWorks virtual I/O "2" driver and creates a TSFS device of the specified name.
- This routine should be called exactly once, before any reads, writes, or opens. Normally, it is called by *usrRoot()* in *usrConfig.c*, and the device name created is */tgtsvr*.
- After this routine has been called, individual virtual I/O channels can be opened by appending the host file name to the virtual I/O device name. For example, to get a file descriptor for the host file */etc/passwd*, call *open()* as follows:
- ```
fd = open ("/tgtsvr/etc/passwd", O_RDWR, 0)
```
- RETURNS** OK, or ERROR if the driver can not be installed.
- SEE ALSO** *wdbTsfsDrv*

wdbUlipPktDevInit()

- NAME** *wdbUlipPktDevInit()* – initialize the WDB agent's communication functions for ULIP
- SYNOPSIS**
- ```
void wdbUlipPktDevInit
(
 WDB_ULIP_PKT_DEV * pDev, /* ULIP packet device to initialize */
 char * ulipDev, /* name of UNIX device to use */
 void (* stackRcv)() /* routine to call when a packet arrives */
)
```
- DESCRIPTION**
- This routine initializes a ULIP device for use by the WDB debug agent. It provides a communication path to the debug agent which can be used with both a task and an external mode agent. It is typically called by *usrWdb.c* when the WDB agent's lightweight ULIP communication path is selected.
- RETURNS** N/A

SEE ALSO `wdbUlipPktDrv`

---

## *wdbUserEvtLibInit()*

**NAME** `wdbUserEvtLibInit()` – include the WDB user event library

**SYNOPSIS** `void wdbUserEvtLibInit (void)`

**DESCRIPTION** This null routine is provided so that `wdbUserEvtLib` can be linked into the system. If `INCLUDE_WDB_USER_EVENT` is defined in `configAll.h`, `wdbUserEvtLibInit` is called by the WDB config routine, `wdbConfig()`, in `usrWdb.c`.

**RETURNS** N/A

**SEE ALSO** `wdbUserEvtLib`

---

## *wdbUserEvtPost()*

**NAME** `wdbUserEvtPost()` – post a user event string to host tools.

**SYNOPSIS** `STATUS wdbUserEvtPost`  
`(`  
`char * event /* event string to send */`  
`)`

**DESCRIPTION** This routine posts the string *event* to host tools that have registered for it. Host tools will receive a USER WTX event string. The maximum size of the event is `WDB_MAX_USER_EVT_SIZE` (defined in `$WIND_BASE/target/h/wdb/wdbLib.h`).

**EXAMPLE** The code below sends a WDB user event to host tools :

```
char * message = "Alarm: reactor overheating !!!";
if (wdbUserEvtPost (message) != OK)
 printf ("Can't send alarm message to host tools");
```

This event will be received by host tools that have registered for it. For example a WTX TCL based tool would do :

```
wtxtcl> wtxToolAttach EP960CX
EP960CX_ps@sevre
```

**wdbVioDrv()**

```

wtxctl> wtxRegisterForEvent "USER.*"
0
wtxctl> wtxEventGet
USER Alarm: reactor overheating !!!

```

Host tools can register for more specific user events :

```

wtxctl> wtxToolAttach EP960CX
EP960CX_ps@sevre
wtxctl> wtxRegisterForEvent "USER Alarm.*"
0
wtxctl> wtxEventGet
USER Alarm: reactor overheating !!!

```

In this piece of code, only the USER events beginning with "Alarm" will be received.

- RETURNS** OK upon successful completion, a WDB error code if unable to send the event to the host or ERROR if the size of the event is greater than `WDB_MAX_USER_EVT_SIZE`.
- SEE ALSO** `wdbUserEvtLib`

---

## **wdbVioDrv()**

- NAME** `wdbVioDrv()` – initialize the tty driver for a WDB agent
- SYNOPSIS**
- ```

STATUS wdbVioDrv
(
    char * name
)

```
- DESCRIPTION**
- This routine initializes the VxWorks virtual I/O driver and creates a virtual I/O device of the specified name.
- This routine should be called exactly once, before any reads, writes, or opens. Normally, it is called by `usrRoot()` in `usrConfig.c`, and the device name created is `"/vio"`.
- After this routine has been called, individual virtual I/O channels can be open by appending the channel number to the virtual I/O device name. For example, to get a file descriptor for virtual I/O channel `0x1000017`, call `open()` as follows:
- ```

fd = open ("/vio/0x1000017", O_RDWR, 0)

```
- RETURNS** OK, or ERROR if the driver cannot be installed.
- SEE ALSO** `wdbVioDrv`

---

## *wdCancel()*

**NAME** *wdCancel()* – cancel a currently counting watchdog

**SYNOPSIS**

```
STATUS wdCancel
(
 WDOG_ID wdId /* ID of watchdog to cancel */
)
```

**DESCRIPTION** This routine cancels a currently running watchdog timer by zeroing its delay count. Watchdog timers may be canceled from interrupt level.

**RETURNS** OK, or ERROR if the watchdog timer cannot be canceled.

**SEE ALSO** *wdLib*, *wdStart()*

---

## *wdCreate()*

**NAME** *wdCreate()* – create a watchdog timer

**SYNOPSIS**

```
WDOG_ID wdCreate (void)
```

**DESCRIPTION** This routine creates a watchdog timer by allocating a WDOG structure in memory.

**RETURNS** The ID for the watchdog created, or NULL if memory is insufficient.

**SEE ALSO** *wdLib*, *wdDelete()*

---

## *wdDelete()*

**NAME** *wdDelete()* – delete a watchdog timer

**SYNOPSIS**

```
STATUS wdDelete
(
 WDOG_ID wdId /* ID of watchdog to delete */
)
```

## ***wdShow()***

- DESCRIPTION** This routine de-allocates a watchdog timer. The watchdog will be removed from the timer queue if it has been started. This routine complements *wdCreate()*.
- RETURNS** OK, or ERROR if the watchdog timer cannot be de-allocated.
- SEE ALSO** *wdLib*, *wdCreate()*

---

## ***wdShow()***

**NAME** *wdShow()* – show information about a watchdog

**SYNOPSIS**

```
STATUS wdShow
(
 WDOG_ID wdId /* watchdog to display */
)
```

**DESCRIPTION** This routine displays the state of a watchdog.

**EXAMPLE** A summary of the state of a watchdog is displayed as follows:

```
-> wdShow myWdId
Watchdog Id : 0x3dd46c
State : OUT_OF_Q
Ticks Remaining : 0
Routine : 0
Parameter : 0
```

**RETURNS** OK or ERROR.

**SEE ALSO** *wdShow*, *VxWorks Programmer's Guide: Target Shell*, *windsh*, *Tornado User's Guide: Shell*

---

## ***wdShowInit()***

**NAME** *wdShowInit()* – initialize the watchdog show facility

**SYNOPSIS**

```
void wdShowInit (void)
```

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | This routine links the watchdog show facility into the VxWorks system. It is called automatically when the watchdog show facility is configured into VxWorks using either of the following methods: <ul style="list-style-type: none"><li>– If you use the configuration header files, define <code>INCLUDE_SHOW_ROUTINES</code> in <code>config.h</code>.</li><li>– If you use the Tornado project facility, select <code>INCLUDE_WATCHDOGS_SHOW</code>.</li></ul> |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>NAME</b>        | <i>wdStart()</i> – start a watchdog timer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <pre>STATUS wdStart (     WDOG_ID wdId,      /* watchdog ID */     int    delay,      /* delay count, in ticks */     FUNCPTR pRoutine, /* routine to call on time-out */     int    parameter /* parameter with which to call routine */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p>This routine adds a watchdog timer to the system tick queue. The specified watchdog routine will be called from interrupt level after the specified number of ticks has elapsed. Watchdog timers may be started from interrupt level.</p> <p>To replace either the timeout <i>delay</i> or the routine to be executed, call <i>wdStart()</i> again with the same <i>wdId</i>; only the most recent <i>wdStart()</i> on a given watchdog ID has any effect. (If your application requires multiple watchdog routines, use <i>wdCreate()</i> to generate separate a watchdog ID for each.) To cancel a watchdog timer before the specified tick count is reached, call <i>wdCancel()</i>.</p> <p>Watchdog timers execute only once, but some applications require periodically executing timers. To achieve this effect, the timer routine itself must call <i>wdStart()</i> to restart the timer on each invocation.</p> |
| <b>WARNING</b>     | The watchdog routine runs in the context of the system-clock ISR; thus, it is subject to all ISR restrictions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>RETURNS</b>     | OK, or ERROR if the watchdog timer cannot be started.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SEE ALSO</b>    | <code>wdLib</code> , <i>wdCancel()</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

***whoami()***

---

***whoami()***

**NAME** *whoami()* – display the current remote identity

**SYNOPSIS** `void whoami (void)`

**DESCRIPTION** This routine displays the user name currently used for remote machine access. The user name is set with *iam()* or *remCurIdSet()*.

**RETURNS** N/A

**SEE ALSO** *remLib*, *iam()*, *remCurIdGet()*, *remCurIdSet()*

---

***wim()***

**NAME** *wim()* – return the contents of the window invalid mask register (SPARC)

**SYNOPSIS** `int wim  
(  
    int taskId /* task ID, 0 means default task */  
)`

**DESCRIPTION** This command extracts the contents of the window invalid mask register from the TCB of a specified task. If *taskId* is omitted or 0, the default task is assumed.

**RETURNS** The contents of the window invalid mask register.

**SEE ALSO** *dbgArchLib*, *VxWorks Programmer's Guide: Target Shell*

---

***winDevInit()***

**NAME** *winDevInit()* – initialize a WIN\_CHAN

**SYNOPSIS** `void winDevInit  
(  
    WIN_CHAN * pChan  
)`

|                    |                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIPTION</b> | This routine initializes the driver function pointers and then resets the chip in a quiescent state. The BSP must have already initialized all the device addresses and the baudFreq fields in the WIN_CHAN structure before passing it to this routine. |
| <b>RETURNS</b>     | N/A                                                                                                                                                                                                                                                      |
| <b>SEE ALSO</b>    | <i>winSio</i>                                                                                                                                                                                                                                            |

## *winIntRcv()*

|                    |                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>winIntRcv()</i> – handle a channel's receive-character interrupt                                                                                       |
| <b>SYNOPSIS</b>    | <pre>void winIntRcv (     WIN_CHAN * pChan, /* channel generating the interrupt */     UINT16    wparam /* message args get passed if you look */ )</pre> |
| <b>DESCRIPTION</b> | This function is attached to the simulator's interrupt handler, and passes the character received in the message to the callback.                         |
| <b>RETURNS</b>     | N/A                                                                                                                                                       |

***winIntTx()***

SEE ALSO [winSio](#)

---

***winIntTx()***

**NAME** *winIntTx()* – transmit a single character.

**SYNOPSIS**

```
void winIntTx
(
 WIN_CHAN * pChan /* channel generating the interrupt */
)
```

**DESCRIPTION** This displays a single character to the simulator's window.

**RETURNS** N/A

**SEE ALSO** [winSio](#)

---

***write()***

**NAME** *write()* – write bytes to a file

**SYNOPSIS**

```
int write
(
 int fd, /* file descriptor on which to write */
 char * buffer, /* buffer containing bytes to be written */
 size_t nbytes /* number of bytes to write */
)
```

**DESCRIPTION** This routine writes *nbytes* bytes from *buffer* to a specified file descriptor *fd*. It calls the device driver to do the work.

**RETURNS** The number of bytes written (if not equal to *nbytes*, an error has occurred), or ERROR if the file descriptor does not exist, the driver does not have a write routine, or the driver returns ERROR. If the driver does not have a write routine, errno is set to ENOTSUP.

## ***z8530IntRd()***

**NAME** *z8530IntRd()* – handle a receiver interrupt

**SYNOPSIS**

```
void z8530IntRd
(
 Z8530_CHAN * pChan
)
```

**DESCRIPTION** This routine handles read interrupts from the SCC.

**RETURNS** N/A

**SEE ALSO** *z8530Sio*

---

## ***z8530IntWr()***

**NAME** *z8530IntWr()* – handle a transmitter interrupt

**SYNOPSIS**

```
void z8530IntWr
(
 Z8530_CHAN * pChan
)
```

**DESCRIPTION** This routine handles write interrupts from the SCC.

**RETURNS** N/A

**SEE ALSO** *z8530Sio*

---

## ***zbufCreate()***

**NAME** *zbufCreate()* – create an empty zbuf

**SYNOPSIS**

```
ZBUF_ID zbufCreate (void)
```

**zbufCut()**

- DESCRIPTION** This routine creates a zbuf, which remains empty (that is, it contains no data) until segments are added by the zbuf insertion routines. Operations performed on zbufs require a zbuf ID, which is returned by this routine.
- RETURNS** A zbuf ID, or NULL if a zbuf cannot be created.
- SEE ALSO** [zbufLib](#), [zbufDelete\(\)](#)

---

## **zbufCut()**

**NAME** `zbufCut()` – delete bytes from a zbuf

**SYNOPSIS**

```
ZBUF_SEG zbufCut
(
 ZBUF_ID zbufId, /* zbuf from which bytes are cut */
 ZBUF_SEG zbufSeg, /* zbuf segment base for offset */
 int offset, /* relative byte offset */
 int len /* number of bytes to cut */
)
```

- DESCRIPTION** This routine deletes *len* bytes from *zbufId* starting at the specified byte location. The starting location of deletion is specified by *zbufSeg* and *offset*. See the [zbufLib](#) manual page for more information on specifying a byte location within a zbuf. In particular, the first byte deleted is the exact byte specified by *zbufSeg* and *offset*.
- The number of bytes to delete is given by *len*. If this parameter is negative, or is larger than the number of bytes in the zbuf after the specified byte location, the rest of the zbuf is deleted. The bytes deleted may span more than one segment.
- If all the bytes in any one segment are deleted, then the segment is deleted, and the data buffer that it referenced will be freed if no other zbuf segments reference it. No segment may survive with zero bytes referenced.
- Deleting bytes out of the middle of a segment splits the segment into two. The first segment contains the portion of the data buffer before the deleted bytes, while the other segment contains the end portion that remains after deleting *len* bytes.
- This routine returns the zbuf segment ID of the segment just after the deleted bytes. In the case where bytes are cut off the end of a zbuf, a value of `ZBUF_NONE` is returned.

- RETURNS** The zbuf segment ID of the segment following the deleted bytes, or NULL if the operation fails.
- SEE ALSO** [zbufLib](#)

---

## *zbufDelete()*

|                    |                                                                                                                                                                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>zbufDelete()</i> – delete a zbuf                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <pre>STATUS zbufDelete (     ZBUF_ID zbufId /* zbuf to be deleted */ )</pre>                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>This routine deletes any zbuf segments in the specified zbuf, then deletes the zbuf ID itself. <i>zbufId</i> must not be used after this routine executes successfully.</p> <p>For any data buffers that were not in use by any other zbuf, <i>zbufDelete()</i> calls the associated free routine (callback).</p> |
| <b>RETURNS</b>     | OK, or ERROR if the zbuf cannot be deleted.                                                                                                                                                                                                                                                                          |
| <b>SEE ALSO</b>    | <i>zbufLib</i> , <i>zbufCreate()</i> , <i>zbufInsertBuf()</i>                                                                                                                                                                                                                                                        |

## *zbufDup()*

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <i>zbufDup()</i> – duplicate a zbuf                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <pre>ZBUF_ID zbufDup (     ZBUF_ID zbufId, /* zbuf to duplicate */     ZBUF_SEG zbufSeg, /* zbuf segment base for offset */     int offset, /* relative byte offset */     int len /* number of bytes to duplicate */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>This routine duplicates <i>len</i> bytes of <i>zbufId</i> starting at the specified byte location, and returns the zbuf ID of the newly created duplicate zbuf.</p> <p>The starting location of duplication is specified by <i>zbufSeg</i> and <i>offset</i>. See the <b>zbufLib</b> manual page for more information on specifying a byte location within a zbuf. In particular, the first byte duplicated is the exact byte specified by <i>zbufSeg</i> and <i>offset</i>.</p> <p>The number of bytes to duplicate is given by <i>len</i>. If this parameter is negative, or is larger than the number of bytes in the zbuf after the specified byte location, the rest of the zbuf is duplicated.</p> |

Duplication of zbuf data does not usually involve copying of the data. Instead, the zbuf segment pointer information is duplicated, while the data is not, which means that the data is shared among all zbuf segments that reference the data. See the **zbufLib** manual page for more information on copying and sharing zbuf data.

**RETURNS** The zbuf ID of a newly created duplicate zbuf, or NULL if the operation fails.

**SEE ALSO** **zbufLib**

---

## *zbufExtractCopy()*

**NAME** *zbufExtractCopy()* – copy data from a zbuf to a buffer

**SYNOPSIS**

```
int zbufExtractCopy
(
 ZBUF_ID zbufId, /* zbuf from which data is copied */
 ZBUF_SEG zbufSeg, /* zbuf segment base for offset */
 int offset, /* relative byte offset */
 caddr_t buf, /* buffer into which data is copied */
 int len /* number of bytes to copy */
)
```

**DESCRIPTION** This routine copies *len* bytes of data from *zbufId* to the application buffer *buf*.

The starting location of the copy is specified by *zbufSeg* and *offset*. See the **zbufLib** manual page for more information on specifying a byte location within a zbuf. In particular, the first byte copied is the exact byte specified by *zbufSeg* and *offset*.

The number of bytes to copy is given by *len*. If this parameter is negative, or is larger than the number of bytes in the zbuf after the specified byte location, the rest of the zbuf is copied. The bytes copied may span more than one segment.

**RETURNS** The number of bytes copied from the zbuf to the buffer, or ERROR if the operation fails.

**SEE ALSO** **zbufLib**

---

## *zbufInsert()*

**NAME** *zbufInsert()* – insert a zbuf into another zbuf

**SYNOPSIS**

```
ZBUF_SEG zbufInsert
(
 ZBUF_ID zbufId1, /* zbuf to insert zbufId2 into */
 ZBUF_SEG zbufSeg, /* zbuf segment base for offset */
 int offset, /* relative byte offset */
 ZBUF_ID zbufId2 /* zbuf to insert into zbufId1 */
)
```

**DESCRIPTION**

This routine inserts all *zbufId2* zbuf segments into *zbufId1* at the specified byte location. The location of insertion is specified by *zbufSeg* and *offset*. See the **zbufLib** manual page for more information on specifying a byte location within a zbuf. In particular, insertion within a zbuf occurs before the byte location specified by *zbufSeg* and *offset*. Additionally, *zbufSeg* and *offset* must be NULL and 0, respectively, when inserting into an empty zbuf. After all the *zbufId2* segments are inserted into *zbufId1*, the zbuf ID *zbufId2* is deleted. *zbufId2* must not be used after this routine executes successfully.

**RETURNS** The zbuf segment ID for the first inserted segment, or NULL if the operation fails.

**SEE ALSO** *zbufLib*

---

## *zbufInsertBuf()*

**NAME** *zbufInsertBuf()* – create a zbuf segment from a buffer and insert into a zbuf

**SYNOPSIS**

```
ZBUF_SEG zbufInsertBuf
(
 ZBUF_ID zbufId, /* zbuf in which buffer is inserted */
 ZBUF_SEG zbufSeg, /* zbuf segment base for offset */
 int offset, /* relative byte offset */
 caddr_t buf, /* application buffer for segment */
 int len, /* number of bytes to insert */
 VOIDFUNCPTR freeRtn, /* free-routine callback */
 int freeArg /* argument to free routine */
)
```

**zbufInsertCopy()**

- DESCRIPTION** This routine creates a zbuf segment from the application buffer *buf* and inserts it at the specified byte location in *zbufId*.
- The location of insertion is specified by *zbufSeg* and *offset*. See the **zbufLib** manual page for more information on specifying a byte location within a zbuf. In particular, insertion within a zbuf occurs before the byte location specified by *zbufSeg* and *offset*. Additionally, *zbufSeg* and *offset* must be NULL and 0, respectively, when inserting into an empty zbuf.
- The parameter *freeRtn* specifies a free-routine callback that runs when the data buffer *buf* is no longer referenced by any zbuf segments. If *freeRtn* is NULL, the zbuf functions normally, except that the application is not notified when no more zbufs segments reference *buf*. The free-routine callback runs from the context of the task that last deletes reference to the buffer. Declare the *freeRtn* callback as follows (using whatever routine name suits your application):
- ```
void freeCallback
(
    caddr_t    buf,    /* pointer to application buffer */
    int       freeArg /* argument to free routine */
)
```
- RETURNS** The zbuf segment ID of the inserted segment, or NULL if the operation fails.
- SEE ALSO** **zbufLib**

zbufInsertCopy()

- NAME** *zbufInsertCopy()* – copy buffer data into a zbuf
- SYNOPSIS**
- ```
ZBUF_SEG zbufInsertCopy
(
 ZBUF_ID zbufId, /* zbuf into which data is copied */
 ZBUF_SEG zbufSeg, /* zbuf segment base for offset */
 int offset, /* relative byte offset */
 caddr_t buf, /* buffer from which data is copied */
 int len /* number of bytes to copy */
)
```
- DESCRIPTION** This routine copies *len* bytes of data from the application buffer *buf* and inserts it at the specified byte location in *zbufId*. The application buffer is in no way tied to the zbuf after this operation; a separate copy of the data is made.
- The location of insertion is specified by *zbufSeg* and *offset*. See the **zbufLib** manual page for more information on specifying a byte location within a zbuf. In particular, insertion

within a zbuf occurs before the byte location specified by *zbufSeg* and *offset*. Additionally, *zbufSeg* and *offset* must be NULL and 0, respectively, when inserting into an empty zbuf.

**RETURNS** The zbuf segment ID of the first inserted segment, or NULL if the operation fails.

**SEE ALSO** ***zbufLib***

---

## ***zbufLength()***

**NAME** *zbufLength()* – determine the length in bytes of a zbuf

**SYNOPSIS**

```
int zbufLength
(
 ZBUF_ID zbufId /* zbuf to determine length */
)
```

**DESCRIPTION** This routine returns the number of bytes in the zbuf *zbufId*.

**RETURNS** The number of bytes in the zbuf, or ERROR if the operation fails.

**SEE ALSO** ***zbufLib***

---

## ***zbufSegData()***

**NAME** *zbufSegData()* – determine the location of data in a zbuf segment

**SYNOPSIS**

```
caddr_t zbufSegData
(
 ZBUF_ID zbufId, /* zbuf to examine */
 ZBUF_SEG zbufSeg /* segment to get pointer to data */
)
```

**DESCRIPTION** This routine returns the location of the first byte of data in the zbuf segment *zbufSeg*. If *zbufSeg* is NULL, the location of data in the first segment in *zbufId* is returned.

**RETURNS** A pointer to the first byte of data in the specified zbuf segment, or NULL if the operation fails.

**SEE ALSO** ***zbufLib***

## ***zbufSegFind()***

**NAME** *zbufSegFind()* – find the zbuf segment containing a specified byte location

**SYNOPSIS**

```
ZBUF_SEG zbufSegFind
(
 ZBUF_ID zbufId, /* zbuf to examine */
 ZBUF_SEG zbufSeg, /* zbuf segment base for pOffset */
 int * pOffset /* relative byte offset */
)
```

**DESCRIPTION** This routine translates an address within a zbuf to its most local formulation. *zbufSegFind()* locates the zbuf segment in *zbufId* that contains the byte location specified by *zbufSeg* and *\*pOffset*, then returns that zbuf segment, and writes in *\*pOffset* the new offset relative to the returned segment.

If the *zbufSeg*, *\*pOffset* pair specify a byte location past the end of the zbuf, or before the first byte in the zbuf, *zbufSegFind()* returns NULL.

See the **zbufLib** manual page for a full discussion of addressing zbufs by segment and offset.

**RETURNS** The zbuf segment ID of the segment containing the specified byte, or NULL if the operation fails.

**SEE ALSO** **zbufLib**

---

## ***zbufSegLength()***

**NAME** *zbufSegLength()* – determine the length of a zbuf segment

**SYNOPSIS**

```
int zbufSegLength
(
 ZBUF_ID zbufId, /* zbuf to examine */
 ZBUF_SEG zbufSeg /* segment to determine length of */
)
```

**DESCRIPTION** This routine returns the number of bytes in the zbuf segment *zbufSeg*. If *zbufSeg* is NULL, the length of the first segment in *zbufId* is returned.

**RETURNS** The number of bytes in the specified zbuf segment, or ERROR if the operation fails.

SEE ALSO **zbufLib**

---

## *zbufSegNext()*

**NAME** *zbufSegNext()* – get the next segment in a zbuf

**SYNOPSIS**

```
ZBUF_SEG zbufSegNext
(
 ZBUF_ID zbufId, /* zbuf to examine */
 ZBUF_SEG zbufSeg /* segment to get next segment */
)
```

**DESCRIPTION** This routine finds the zbuf segment in *zbufld* that is just after the zbuf segment *zbufSeg*. If *zbufSeg* is NULL, the segment after the first segment in *zbufld* is returned. If *zbufSeg* is the last segment in *zbufld*, NULL is returned.

**RETURNS** The zbuf segment ID of the segment after *zbufSeg*, or NULL if the operation fails.

SEE ALSO **zbufLib**

---

## *zbufSegPrev()*

**NAME** *zbufSegPrev()* – get the previous segment in a zbuf

**SYNOPSIS**

```
ZBUF_SEG zbufSegPrev
(
 ZBUF_ID zbufId, /* zbuf to examine */
 ZBUF_SEG zbufSeg /* segment to get previous segment */
)
```

**DESCRIPTION** This routine finds the zbuf segment in *zbufld* that is just previous to the zbuf segment *zbufSeg*. If *zbufSeg* is NULL, or is the first segment in *zbufld*, NULL is returned.

**RETURNS** The zbuf segment ID of the segment previous to *zbufSeg*, or NULL if the operation fails.

SEE ALSO **zbufLib**

---

## ***zbufSockBufSend()***

**NAME** *zbufSockBufSend()* – create a zbuf from user data and send it to a TCP socket

**SYNOPSIS**

```
int zbufSockBufSend
(
 int s, /* socket to send to */
 char * buf, /* pointer to data buffer */
 int bufLen, /* number of bytes to send */
 VOIDFUNCPTR freeRtn, /* free routine callback */
 int freeArg, /* argument to free routine */
 int flags /* flags to underlying protocols */
)
```

**DESCRIPTION** This routine creates a zbuf from the user buffer *buf*, and transmits it to a previously established connection-based (stream) socket.

The user-provided free routine callback at *freeRtn* is called when *buf* is no longer in use by the TCP/IP network stack. Applications can exploit this callback to receive notification that *buf* is free. If *freeRtn* is NULL, the routine functions normally, except that the application has no way of being notified when *buf* is released by the network stack. The free routine runs in the context of the task that last references the buffer. This is typically either the context of tNetTask, or the context of the caller's task. Declare *freeRtn* as follows (using whatever name is convenient):

```
void freeCallback
(
 caddr_t buf, /* pointer to user buffer */
 int freeArg /* user-provided argument to free routine */
)
```

You may OR the following values into the *flags* parameter with this operation:

**MSG\_OOB** (0x1)

Out-of-band data.

**MSG\_DONTROUTE** (0x4)

Send without using routing tables.

**RETURNS** The number of bytes sent, or ERROR if the call fails.

**SEE ALSO** *zbufSockLib*, *zbufSockSend()*, *send()*

---

## *zbufSockBufSendto()*

**NAME** *zbufSockBufSendto()* – create a zbuf from a user message and send it to a UDP socket

**SYNOPSIS**

```
int zbufSockBufSendto
(
 int s, /* socket to send to */
 char * buf, /* pointer to data buffer */
 int bufLen, /* number of bytes to send */
 VOIDFUNCPTR freeRtn, /* free routine callback */
 int freeArg, /* argument to free routine */
 int flags, /* flags to underlying protocols */
 struct sockaddr * to, /* recipient's address */
 int tolen /* length of to socket addr */
)
```

**DESCRIPTION** This routine creates a zbuf from the user buffer *buf*, and sends it to the datagram socket named by *to*. The socket *s* is the sending socket.

The user-provided free routine callback at *freeRtn* is called when *buf* is no longer in use by the UDP/IP network stack. Applications can exploit this callback to receive notification that *buf* is free. If *freeRtn* is NULL, the routine functions normally, except that the application has no way of being notified when *buf* is released by the network stack. The free routine runs in the context of the task that last references the buffer. This is typically either tNetTask context, or the caller's task context. Declare *freeRtn* as follows (using whatever name is convenient):

```
void freeCallback
(
 caddr_t buf, /* pointer to user buffer */
 int freeArg /* user-provided argument to free routine */
)
```

You may OR the following values into the *flags* parameter with this operation:

**MSG\_OOB** (0x1)  
Out-of-band data.

**MSG\_DONTROUTE** (0x4)  
Send without using routing tables.

**RETURNS** The number of bytes sent, or ERROR if the call fails.

**SEE ALSO** *zbufSockLib*, *zbufSockSendto()*, *sendto()*

## **zbufSockLibInit()**

|                    |                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | <b>zbufSockLibInit()</b> – initialize the zbuf socket interface library                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <code>STATUS zbufSockLibInit (void)</code>                                                                                                                                                                                   |
| <b>DESCRIPTION</b> | This routine initializes the zbuf socket interface library. It must be called before any zbuf socket routines are used. It is called automatically when the configuration macro <code>INCLUDE_ZBUF_SOCKET</code> is defined. |
| <b>RETURNS</b>     | OK, or ERROR if the zbuf socket interface could not be initialized.                                                                                                                                                          |

| <b>NAME</b>        | <b>zbufSockRecv()</b> – receive data in a zbuf from a TCP socket                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <pre>ZBUF_ID zbufSockRecv (     int  s,      /* socket to receive data from */     int  flags, /* flags to underlying protocols */     int * pLen  /* number of bytes requested/returned */ )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | <p>This routine receives data from a connection-based (stream) socket, and returns the data to the user in a newly created zbuf.</p> <p>The <i>pLen</i> parameter indicates the number of bytes requested by the caller. If the operation is successful, the number of bytes received is copied to <i>pLen</i>.</p> <p>You may OR the following values into the <i>flags</i> parameter with this operation:</p> <ul style="list-style-type: none"><li><b>MSG_OOB</b> (0x1)<br/>Out-of-band data.</li><li><b>MSG_PEEK</b> (0x2)<br/>Return data without removing it from socket.</li></ul> <p>Once the user application is finished with the zbuf, <b>zbufDelete()</b> should be called to return the zbuf memory buffer to the VxWorks network stack.</p> |

**RETURNS** The zbuf ID of a newly created zbuf containing the received data, or NULL if the operation fails.

**SEE ALSO** **zbufSockLib**, *recv()*

---

## ***zbufSockRecvfrom()***

**NAME** *zbufSockRecvfrom()* – receive a message in a zbuf from a UDP socket

**SYNOPSIS**

```
ZBUF_ID zbufSockRecvfrom
(
 int s, /* socket to receive from */
 int flags, /* flags to underlying protocols */
 int * pLen, /* number of bytes requested/returned */
 struct sockaddr * from, /* where to copy sender's addr */
 int * pFromLen /* value/result length of from */
)
```

**DESCRIPTION** This routine receives a message from a datagram socket, and returns the message to the user in a newly created zbuf.

The message is received regardless of whether the socket is connected. If *from* is nonzero, the address of the sender's socket is copied to it. Initialize the value-result parameter *pFromLen* to the size of the *from* buffer. On return, *pFromLen* contains the actual size of the address stored in *from*.

The *pLen* parameter indicates the number of bytes requested by the caller. If the operation is successful, the number of bytes received is copied to *pLen*.

You may OR the following values into the *flags* parameter with this operation:

**MSG\_OOB** (0x1)  
Out-of-band data.

**MSG\_PEEK** (0x2)  
Return data without removing it from socket.

Once the user application is finished with the zbuf, *zbufDelete()* should be called to return the zbuf memory buffer to the VxWorks network stack.

**RETURNS** The zbuf ID of a newly created zbuf containing the received message, or NULL if the operation fails.

**SEE ALSO** **zbufSockLib**

---

## ***zbufSockSend()***

**NAME** *zbufSockSend()* – send zbuf data to a TCP socket

**SYNOPSIS**

```
int zbufSockSend
(
 int s, /* socket to send to */
 ZBUF_ID zbufId, /* zbuf to transmit */
 int zbufLen, /* length of entire zbuf */
 int flags /* flags to underlying protocols */
)
```

**DESCRIPTION** This routine transmits all of the data in *zbufId* to a previously established connection-based (stream) socket.

The *zbufLen* parameter is used only for determining the amount of space needed from the socket write buffer. *zbufLen* has no effect on how many bytes are sent; the entire zbuf is always transmitted. If the length of *zbufId* is not known, the caller must first determine it by calling *zbufLength()*.

This routine transfers ownership of the zbuf from the user application to the VxWorks network stack. The zbuf ID *zbufId* is deleted by this routine, and should not be used after the routine is called, even if an ERROR status is returned. (Exceptions: when the routine fails because the zbuf socket interface library was not initialized or an invalid zbuf ID was passed in, in which case there is no zbuf to delete. Moreover, if the call fails during a non-blocking I/O socket write with an **errno** of **EWOULDBLOCK**, then *zbufId* is not deleted; thus the caller may send it again at a later time.)

You may OR the following values into the *flags* parameter with this operation:

**MSG\_OOB** (0x1)

Out-of-band data.

**MSG\_DONTROUTE** (0x4)

Send without using routing tables.

**RETURNS** The number of bytes sent, or ERROR if the call fails.

**SEE ALSO** *zbufSockLib*, *zbufLength()*, *zbufSockBufSend()*, *send()*

---

## *zbufSockSendto()*

**NAME** *zbufSockSendto()* – send a zbuf message to a UDP socket

**SYNOPSIS**

```
int zbufSockSendto
(
 int s, /* socket to send to */
 ZBUF_ID zbufId, /* zbuf to transmit */
 int zbufLen, /* length of entire zbuf */
 int flags, /* flags to underlying protocols */
 struct sockaddr * to, /* recipient's address */
 int tolen /* length of to socket addr */
)
```

**DESCRIPTION** This routine sends the entire message in *zbufId* to the datagram socket named by *to*. The socket *s* is the sending socket.

The *zbufLen* parameter is used only for determining the amount of space needed from the socket write buffer. *zbufLen* has no effect on how many bytes are sent; the entire zbuf is always transmitted. If the length of *zbufId* is not known, the caller must first determine it by calling *zbufLength()*.

This routine transfers ownership of the zbuf from the user application to the VxWorks network stack. The zbuf ID *zbufId* is deleted by this routine, and should not be used after the routine is called, even if an ERROR status is returned. (Exceptions: when the routine fails because the zbuf socket interface library was not initialized or an invalid zbuf ID was passed in, in which case there is no zbuf to delete. Moreover, if the call fails during a non-blocking I/O socket write with an **errno** of **EWOULDBLOCK**, then *zbufId* is not deleted; thus the caller may send it again at a later time.)

You may OR the following values into the *flags* parameter with this operation:

**MSG\_OOB** (0x1)  
Out-of-band data.

**MSG\_DONTROUTE** (0x4)  
Send without using routing tables.

**RETURNS** The number of bytes sent, or ERROR if the call fails.

**SEE ALSO** *zbufSockLib*, *zbufLength()*, *zbufSockBufSendto()*, *sendto()*

## ***zbufSplit()***

**NAME** *zbufSplit()* – split a zbuf into two separate zbufs

**SYNOPSIS**

```
ZBUF_ID zbufSplit
(
 ZBUF_ID zbufId, /* zbuf to split into two */
 ZBUF_SEG zbufSeg, /* zbuf segment base for offset */
 int offset /* relative byte offset */
)
```

**DESCRIPTION** This routine splits *zbufId* into two separate zbufs at the specified byte location. The first portion remains in *zbufId*, while the end portion is returned in a newly created zbuf. The location of the split is specified by *zbufSeg* and *offset*. See the **zbufLib** manual page for more information on specifying a byte location within a zbuf. In particular, after the split operation, the first byte of the returned zbuf is the exact byte specified by *zbufSeg* and *offset*.

**RETURNS** The zbuf ID of a newly created zbuf containing the end portion of *zbufId*, or NULL if the operation fails.

**SEE ALSO** **zbufLib**
